SELECTED WATER RESOURCES ABSTRACTS (SWRA) is produced by the Office of Water Research and Technology, U.S. Department of the Interior, and published monthly by the National Technical Information Service (NTIS), U.S. Department of Commerce.

SWRA is available to Federal agencies and their contractors or grantees in water resources research upon request, citing contract or grant number and sponsoring agency. Write: Office of Water Research and Technology, U.S. Department of the Interior, Washington, DC 20240. The **SWRA Journal** is also available on subscription from NTIS, 5285 Port Royal Road, Springfield, VA 22161. Annual subscription rates for the North American Continent are: Journal only, $100; Journal and Annual Indexes, $125; Indexes only, $50. Other addressees, write for prices.

Some documents abstracted in this journal can be purchased from NTIS. Price codes are given in the entries and a current code-price conversion table is printed on the outside back cover. Other documents are available from originating organizations or authors as indicated in the citation.

SELECTED WATER RESOURCES ABSTRACTS

A monthly publication of the Office of Water Research and Technology,
U.S. Department of the Interior

VOLUME 15, NUMBER 10
OCTOBER 1, 1982

W82-04251 -- W82-04750

The Secretary of the Interior has determined that the publication of the periodical is necessary in the transaction of the public business required by law of this Department.

LIBRARY U. OF I., URBANA-CHAMPAIGN

As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This includes fostering the wisest use of our land and water resources, protecting our fish and wildlife, preserving the environmental and cultural values of our national parks and historical places, and providing for the enjoyment of life through outdoor recreation. The Department assesses our energy and mineral resources and works to assure that their development is in the best interests of all our people. The Department also has a major responsibility for American Indian reservation communities and for people who live in Island Territories under U.S. administration.

I. 04/2:
6/10-12

PREFACE

Selected Water Resources Abstracts, a monthly journal, includes abstracts of current and earlier pertinent monographs, journal articles, reports, and other publication formats. These documents cover water resources as treated in the life, physical, and social sciences and the related engineering and legal aspects of the characteristics, supply condition, conservation, control, use, or management of water resources. Each abstract includes a full bibliographic citation and a set of descriptors which are listed in the **Water Resources Thesaurus.** The abstract entries are classified into 10 fields and 60 groups similar to the water resources research categories established by the Committee on Water Resources Research of the then Federal Council for Science and Technology.

Selected Water Resources Abstracts is designed to serve the scientific and technical information needs of scientists, engineers, and managers as one of several services of the Office of Water Research and Technology. The cumlative SWRA file from 1968 and monthly updates are available also in magnetic tape through lease from NTIS.

THE OFFICE OF WATER RESEARCH AND TECHNOLOGY DOES NOT PROVIDE COPIES OF DOCUMENTS ABSTRACTED IN THIS JOURNAL. Sufficient bibliographic information is given to enable readers to order the desired documents from local libraries or other sources.

Comments and suggestions concerning the contents and arrangement of this bulletin are welcome.

CONTENTS

SUBJECT FIELDS AND GROUPS

Please use the edge index on the back cover to locate Subject Fields and Indexes.

01 NATURE OF WATER

Includes the following Groups: Properties; Aqueous Solutions and Suspensions.

02 WATER CYCLE

Includes the following Groups: General; Precipitation; Snow, Ice, and Frost; Evaporation and Transpiration; Streamflow and Runoff; Groundwater; Water in Soils; Lakes; Water in Plants; Erosion and Sedimentation; Chemical Processes; Estuaries.

03 WATER SUPPLY AUGMENTATION AND CONSERVATION

Includes the following Groups: Saline Water Conversion; Water Yield Improvement; Use of Water of Impaired Quality; Conservation in Domestic and Municipal Use; Conservation in Industry; Conservation in Agriculture.

04 WATER QUANTITY MANAGEMENT AND CONTROL

Includes the following Groups: Control of Water on the Surface; Groundwater Management; Effects on Water of Man's Nonwater Activities; Watershed Protection.

05 WATER QUALITY MANAGEMENT AND PROTECTION

Includes the following Groups: Identification of Pollutants; Sources of Pollution; Effects of Pollution; Waste Treatment Processes; Ultimate Disposal of Wastes; Water Treatment and Quality Alteration; Water Quality Control.

06 WATER RESOURCES PLANNING

Includes the following Groups: Techniques of Planning; Evaluation Process; Cost Allocation, Cost Sharing, Pricing/Repayment; Water Demand; Water Law and Institutions; Nonstructural Alternatives; Ecologic Impact of Water Development.

07 RESOURCES DATA

Includes the following Groups: Network Design; Data Acquisition; Evaluation, Processing and Publication.

08 ENGINEERING WORKS

Includes the following Groups: Structures; Hydraulics; Hydraulic Machinery; Soil Mechanics; Rock Mechanics and Geology; Concrete; Materials; Rapid Excavation; Fisheries Engineering.

09 MANPOWER, GRANTS, AND FACILITIES

Includes the following Groups: Education—Extramural; Education—In-House; Research Facilities; Grants, Contracts, and Research Act Allotments.

10 SCIENTIFIC AND TECHNICAL INFORMATION

Includes the following Groups: Acquisition and Processing; Reference and Retrieval; Secondary Publication and Distribution; Specialized Information Center Services; Translations; Preparation of Reviews.

THE GEOTHERMAL HYDROLOGY OF WARNER VALLEY, OREGON: A RECONNAISSANCE STUDY,
Geological Survey, Menlo Park, CA. Water Resources Div.
E. A. Sammel, and R. W. Craig.
Available from Supt. of Documents, GPO, Washington, DC 20402, Price, $4.00. Geological Survey Professional Paper 1044-I, 1981. 47 p, 21 Fig, 1 Plate, 9 Tab, 71 Ref.

Descriptors: *Geothermal studies, *Groundwater, *Thermal water, *Thermal properties, Aquifer characteristics, Geohydrology, Geochemistry, Warm springs, Heat flow, Thermocline, Geophysics, *Oregon, *Warner Valley.

Warner Valley, a high-desert valley situated in the Basin and Range province of south-central Oregon, contains thermal waters that are currently discharged from at least 30 springs and wells. The waters originate as local meteoric water which circulates to depths of 13,000 feet or more in faults and fault intersections in Tertiary basaltic flow rocks and tuffaceous sediments. The thermal waters are of two chemical types: sodium chloride and sodium bicarbonate waters. Temperatures in the hotter sodium chloride waters are known to be as high as 127 C; the cooler sodium bicarbonate waters are highly mixed with recharge water and have temperatures in the range 20 C to 40 C. Geothermometers and mixing models indicate that temperatures of equilibration are at least 170 C for the thermal components of the hotter waters. Conductive heat flow through the valley-fill deposits is estimated to be 75 milliwatts per square meter and the normal thermal gradient in the valley may be about 40 C per kilometer, both slightly low for the Basin and Range province. The size and location of the geothermal reservoirs are unknown. If a single reservoir underlies the two principal areas of thermal discharge, total heat stored in the reservoir above a base temperature of 10 C may be about 1.6 x 10 to the 19th power joules. If, however, the thermal fluids at depth are restricted to the major boundary faults, the stored heat at high temperatures may be about 5 x 10 to the 16th power joules. Recoverable heat at lower temperatures from depths less than 1,000 feet in the valley-fill deposits may also be about 5 x 10 to the 16th power joules. (USGS)

INTERPRETATION OF CHEMICAL ANALYSES OF WATER COLLECTED FROM TWO GEOTHERMAL WELLS AT COSO, CALIFORNIA,
Geological Survey, Menlo Park, CA.
R. O. Fournier, J. M. Thompson, and C. F. Austin.
Journal of Geophysical Research, Vol 85, No B5, p 2405-2410, May 10, 1980. 1 Fig, 1 Tab, 17 Ref.

Descriptors: *Geothermal studies, *Chemical analysis, *Water analysis, *Hot springs, Water temperature, Wells, Chlorides, Groundwater reservoirs, Coso, *California.

Wellhead and downhole water samples from two wells drilled for geothermal energy exploration were sampled and analyzed in an effort to predict reservoir temperatures and fluid characteristics in still unexplored parts of the system. The first well, Coso No. 1 located at Coso hot springs in California, had been drilled to a depth of 114.3 eters. The second well, CGEH No. 1 located 3.2 kilometers to the west, had been drilled to a depth of 1477 meters. The same chloride concentration is present in hot waters entering each of the wells (about 2350 milligrams per kilogram), indicating that a body of uniformly chloride-rich hot water is present at depth in the Coso geothermal system. The maximum measured temperatures were 142 C in the Coso No. 1 well and 195 C in the CGEH No. 1 well. Cation and sulfate isotope geothermometers indicate that the reservoir feeding water to the Coso hot spring has a temperature of about 240 C to 250 C, and that the reservoir feeding the CGEH well has a temperature of about 205 C. The fumarole, acid-sulfate pool, and shallow steam well expressions of hydrothermal activity in the area give a false indication of an extensive vapor-dominated system since the upward convecting, boiling, alkaline-chloride waters do not reach the surface. The presence of a chloride-rich hot water system rather than a vapor-dominated system should be considered when interpreting geophysical data and calculating the economics of exploiting the geothermal energy resource. (Carroll-FRC)

A MODEL OF HYDROTHERMAL CONVECTION IN AN AQUIFER,
Sibley School of Mechanical and Aerospace Engineering, Ithaca, NY.
K. E. Torrance, V. W. C. Chan, and D. L. Turcotte.
Journal of Geophysical Research, Vol 85, No B5, p 2554-2558, May 10, 1980. 6 Fig, 1 Tab, 28 Ref.

Descriptors: *Hydrothermal studies, *Aquifers, Thermal conductivity, Turbulent flow, *Geothermal studies, Laminar flow, Transition flow, Velocity, Mathematical models, Numerical analysis.

Numerical calculations were conducted to determine the temperature distribution resulting from the steady state hydrothermal flow of water through a smoothly curved cylindrical aquifer. The outflow water temperature was found to be closest to the ambient temperature at the base of the aquifer at intermediate flow rates. Low flow velocities resulted in the cooling of the water by conduction to the wall rock before it reached the surface, while high flow velocity did not allow the water time to be heated by conduction from the wall rock. The transition from laminar to turbulent flow was found to reduce the flow through the aquifer and the temperature of the outflow water. Outflow temperatures were generally found to be too low to explain continental hot springs. Shallow laminar hydrothermal flows were shown to be more effective in transporting heat to the surface than deeper turbulent flows. These results suggest that very shallow (less than 100 meter) hydrothermal flows of seawater in the oceanic crust may be responsible for the reduction and variability of the measured near-surface geothermal gradient. RELATION BETWEEN CURVE NUMBER AND RUNOFF COEFFICIENT,
Maryland Univ., College Park. Coll. of Engineering.
R. H. McCuen, and T. R. Bondelid.
Journal of the Irrigation and Drainage Division, Proceedings of the American Society of Civil Engineers, Vol 107, No IR4, p 395-400 December, 1981. 1 Fig, 1 Tab, 6 Ref.

Descriptors: *Watersheds, *Graphical methods, *Land use, *Computer models, Model studies, Graphical analysis, Mathematical studies, Mathematical models, *Runoff, Peak discharge, Hydrologic models.

Two peak discharge methods, the rational formula and the TR-55 graphic method, are based on similar input data and give similar peak discharge estimates when land use is similar. Peak discharge estimates by the rational formula are more sensitive to runoff coefficient (C) values than are TR-55 estimates to the runoff curve number (CN). The graphical method is based on the conceptual framework of the RUNOFF subroutine of the Soil conservation Service (SCS) TR-20 computer program, which should form peak discharges similar to those obtained with the rational formula. Disparities in land use values create C values that are higher than normally acceptable. This bias should be taken into account when design projects are controlled by different policies. For residential and open space land use categories, the graphical method generally provides higher peak discharge estimates than the rational method. The SCS methods, including the TR-55 graphical method, ae based on a 24 hr storm distribution and do not necessarily have to include a bias in estimating the peak discharge. (Geiger-FRC)

YOUNG'S INEQUALITY FOR THREE-DIMENSIONAL FLOWS,
Public Power Corp., Athens (Greece). Computing Center.
A. T. Marinos.
Journal of the Irrigation and Drainage Division, Proceedings of the American Society of Civil Engineers, Vol 107, No IR4, p 388-394, December, 1981. 2 Fig, 1 Tab, 3 Ref.

Descriptors: *Mathematical equations, *Drainage, *Precipitation intensity, *Flow profiles, Mathematical models, Darcys law, Youngs modulus, Water table, *Porosity.

Young's inequality for steady drainage through a porous strip contained between two parallel ditches is useful for relating the height of the water table at its center, the precipitation intensity, the ditch spacing, and the level of permanent water horizon. An extension of Young's inequality to three-dimensional flow is presented which may be applied to calculate the limits on precipitation intensity for steady flows so that the maximum height of the water will not exceed a prescribed value. The equations for calculating these bounds take on closed type formulas when the steady drainage takes place through regular (rectangular) cross sections and the precipitation intensity is such that a formal solution of the partial differential equation is possible. (Geiger-FRC)
W82-04267

PROBLEMS OF MODELLING A HIGH MOUNTAINOUS DRAINAGE BASIN WITH PREDOMINANT SNOW YIELDS,
Grenoble-1 Univ. (France). Inst. de Mecanique.
R. Charbonneau, J.-P. Lardeau, and C. Obled.
Hydrological Sciences Bulletin, Vol 26, No 4, p 345-361, December, 1981. 11 Fig, 4 Tab, 14 Ref.

Descriptors: *Hydrologic models, *Snowmelt, *Hydrologic cycle, *Catchment areas, Model studies, Evapotranspiration, Evaporation, Energy, Air temperature, Physiographic balance, Drainage area, Precipitation, Snow, Mountains, *Durance River basin, *French Alps.

Three snowmelt and evapotranspiration models for a high mountain drainage basin of the Durance River in the French Alps were developed and compared. The Durance model was specifically designed for the basin and used a refined description of the physiographic features and snowmelt routine based on energy budgets at 12 hr intervals. The HSP general purpose hydrological model was partially standardized and showed the best four-year adjustment due to its large number of degrees of freedom. An intermediate model kept all the parameter values of the HSP model, but did not benefit from a heat budget component. This modified HSP model receives air temperature values from a main program which has been shown to systematically underestimate the maximum temperature which influences snowmelt. The ready-made models took almost as long to set up and adjust as the Durance model. Major errors in calculations did not occur in the modelling of the hydrological cycle but rather in peripheral parameters dealing with data estimation or extrapolation.

LIBRARY U. OF I. - URBANA CHAMPAIGN

It was suggested that standardized procedures for the estimation of missing model data be avoided and replaced by objective analyses of precipitation, snow cover and temperature fields of the drainage basin. (Geiger-(FRC)
W82-04303

RELATIVE RUNOFF BY CURVE NUMBER NOMOGRAPH,
New Mexico Univ., Albuquerque. Dept. of Civil Engineering.
R. J. Heggen.
Journal of the Irrigation and Drainage Division, Proceedings of the American Society of Civil Engineers, Vol 107, No IR4, p 385-388, December, 1981. 1 Fig, 10 Ref.

Descriptors: *Graphical methods, *Watersheds, *Mathematical models, *Storm runoff, *Discharge measurement, Graphical analysis, Runoff, Model studies, Runoff, Precipitation, Mathematical equations, Mathematical studies, *Channel morphology.

The graphical solution for relative discharge allows rapid estimation of runoff changes due to watershed modifications and visual evaluation of the sensitivity of runoff change to the Soil Conservation Service curve number (CN) modifications and storm precipitation. An equation for relative runoff may be used for a more accurate calculation; however, an analysis based on curve numbers should be regarded as only an approximate solution. The relative runoff equation may be solved by graphical methods. Vertical and horizontal nomographs are used to intersect two specific sections of the rectangular chart, and the curve corresponding to the Cartesian coordinate defined by these two intersections represents the relative runoff. Graphical analysis of relative change provides a pragmatic basis for anticipating runoff modification for problems where actual discharge can be measured or estimated by alternative methods. (Geiger-FRC)

THE GENERAL HYDROLOGIC SYSTEM MODEL,
Mississippi State Univ., Mississippi State. Dept. of Mathematics.
R. C. McCann, and V. P. Singh.
Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 107, No HY12, 1581-1592, December, 1981. 3 Fig, 14 Ref.

Descriptors: *Hydrographs, *Storm runoff, *Hydrologic models, General Hydrologic System model, Model studies, Runoff, Rainfall-runoff relationships, Excess rainfall, Chow and Kulandaiswamy model.

Improvements and simplifications are suggested for Chow and Kulandaiswamy's General Hydrologic System model. The problem of negative instantaneous unit hydrographs, arising from the inconsistencies in the derivations and initial conditions, was solved by assuming an instant unit hydrograph of zero at zero time. This caused coefficients associated with derivatives of excess rainfall to vanish. (Cassar-FRC)
W82-04314

TWO-DIMENSIONAL SOIL MOISTURE FLOW IN A SLOPING RECTANGULAR REGION: EXPERIMENTAL AND NUMERICAL STUDIES,
Texas A and M Univ., College Station. Dept. of Agricultural Engineering.
J. L. Nieber, and M. F. Walter.
Water Resources Research, Vol 17, No 6, p 1722-1730, December, 1981. 12 Fig, 23 Ref.

Descriptors: *Soil water, *Slopes, *Infiltration, Numerical analysis, Hydrographs, Flumes, Rainfall infiltration, Capillarity.

The two-dimensional flow of soil moisture under the conditions of rainfall infiltration was studied in a hillslope soil moisture flow laboratory model composed of a flume (3.66 x 0.58 x 0.108 m) filled with sand. Experimental results, expressed as hydraulic head fields and runoff hydrographs, agreed well with results from a numerical solution after the effects of capillary hysteresis were incorporated into the numerical solution. Without considering the capillary hysteresis the numerically simulated hydrograph lagged behind the experimental hydrograph to a significant degree. the numerical technique was derived from a finite element-finite difference solution of the Richards equation. (Cassar-FRC)
W82-04333

STORM RUNOFF ANALYSES ON THREE SEMI-ARID CATCHMENTS,
Rhodes Univ., Grahamstown (South Africa). Dept. of Geography.
D. L. Murray, and A. H. M. Gorgens.
Water SA, Vol 7, No 4, p 223-233, October, 1981. 6 Fig, 6 Tab, 16 Ref.

Descriptors: *Storm runoff, *Rainstorms, *Hydrographs, *Semiarid lands, Rainfall-runoff relationships, Statistical analysis, Ecca River, Grahamstown, *South Africa, Runoff, Rainfall intensity, Evaporation, Streamflow, Antecedent moisture, Peak flow.

A statistical analysis of storm rainfall and streamflow data (1975-1979) from 3 semiarid catchments in the Ecca River region, South Africa, produced preliminary equations for predicting storm hydrograph characteristics. The best index of catchment wetness at the beginning of a storm was generally the seven-day antecedent rainfall. Storm flow volume was predicted using seven-day antecedent rainfall and storm rainfall. Storm flow peak and storm flow duration were obtained from predicted storm flow volume. Independent variables considered in this study were storm rainfall, rainfall duration, maximum intensity of rainfall, antecedent flow, and antecedent rainfall and moisture indices calculated by accumulating rainfall and potential evaporation over varying periods prior to storms. (Cassar-FRC)
W82-04339

HYDROGEOLOGIC EVALUATION OF WETLAND BASINS FOR LAND USE PLANNING,
Lowell Univ., MA. Dept. of Earth Sciences.
A. L. O'Brien, and W. S. Motts.
Water Resources Bulletin, Vol 16, No 5, p 785-789, October, 1980. 3 Fig, 1 Tab, 11 Ref.

Descriptors: *Wetlands, *Classification, *Land use, *Groundwater potential, Geohydrology, Geology, Topography, Geomorphology, Water quality, Aquifers, Hydrology.

Since wetlands vary according to geologic, hydrologic and topographic settings, a wetland classification based on these factors which modify hydrologic response is proposed to provide a good framework for evaluation of wetland research in relation to land use planning. Wetlands affect the potential for groundwater development in wetland dominated basin, modify the character of runoff from a basin and influence the discharge/recharge relationship with the underlying aquifer. Some geologic and hydrologic factors which might allow distinction between wetlands include the character and thinkness of surficial materials, bedrock type, hydrologic position, permeability of the organic layer, transmissivity, water quality, aquifer structure, groundwater outflows and depth of standing water. Some distinguishing topographic features of wetlands are position in the drainage basin, relative size, and absolute size of wetlands. Application of the proposed classification scheme to wetlands in the northeastern United States produced two realistic geologic types that could be expected to be encountered. Matrices of these two types produced 25 categories of wetlands, 13 of which are common types. These types should be further tested to define their hydrologic function in this classification scheme. (Geiger-FRC)
W82-04439

ANALYSIS OF DETENTION BASIN SYSTEMS,
Monash Univ., Clayton (Australia).
R. G. Mein.
Water Resources Bulletin, Vol 16, No 5, p 824-829, October, 1980. 7 Fig, 1 Tab, 13 Ref.

Descriptors: *Mathematical models, *Detention reservoirs, *Design criteria, *Flood peak, *Flood-control storage, Hydrologic models, Model studies, Catchment basins, Flood hydrographs, Storm runoff, Flood routing, Simulation analysis, Mathematical studies.

Simple procedures of designing detention basins to reduce peak flows on rivers and streams are often limited in scope. A more complicated routing model is described, and its application to an urban basin system at Gardiners Creek, Australia is examined. The model computes design inflow hydrographs and routes flow downstream to the next point of interest. The catchment is divided into subcatchments along watershed lines, excess rainfall is calculated from the temporal pattern of the nearest recording rain gauge, and the depth is obtained from the isohyetal map of the storm event. Catchment storage effects are simulated by routing flows between subcatchments through simple nonlinear storage elements. The present model was found suitable for examining basins in series or in parallel. Although it seems unlikely that the addition of a basin would increase flood peaks downstream to any significant extent, it still may be possible for a particular combination of basins to have this effect. It is therefore suggested that multibasin systems be fully investigated under various storm events to assess the individual contribution of each basin to flood mitigation. (Geiger-FRC)
W82-04444

COMPARISON OF MODELS FOR FORECASTING SNOWMELT RUNOFF VOLUMES,
Maryland Univ., College Park. Dept. of Civil Engineering.
M. E. Hawley, R. H. McCuen, and A. Rango.
Water Resources Bulletin, Vol 16, No 5, p 914-920, October, 1980. 4 Tab, 8 Ref.

Descriptors: *Snowmelt, *Runoff-forecasting, *Model studies, Mathematical studies, Water supply, Remote sensing, Hydrologic models, Comparison studies.

Available snowmelt models were tested for accuracy on a single watershed using the same data base. Specific analyses were made for determining the value of Landsat derived snow covered area (SCA) data in the various runoff prediction models; to investigate the value of subdividing the watershed into smaller, more homogeneous areas; to determine the effect of delays in data collection such as that which might occur in the compilation and analysis of Landsat data; to evaluate the accuracy of forecasts based solely on SCA measurements; and to determine the length of record required for model calibration. Models tested include the Regression model, the Water Balance model, and the Martinec model. Accuracy of the Tangborn model and the regression models was greater if the test data fell within the range of calibration data rather than outside. Regression models were significantly more accurate for forecasts of 60 days or more than for shorter periods. The Tangborn model was more accurate for forecasts of 90 days or more. The Martinec model was more accurate for forecasts of 1, 2, 3, 5, 10, or 15 days. Accuracy of long term models was independent of forecast data. The short term models were least accurate for forecast periods in late May and early June. The Martinec model was the best of those tested for one and two day forecasts. Regression models were roughly equal in accuracy. Spatial separation of the watershed by elevation zones did not improve the accuracy of the Martinec model in the Kings River basin. Delays in data collection of more than one day may sig-

nificantly lessen the accuracy of the Martinec model. (Baker-FRC)

PREDICTION OF WATER INFLOW TO LAKE MEMPHREMAGOG (PREVISION DES APPORTS HYDRIQUES AU LAC MEMPHREMAGOG),
Ministere de l'Environnement, Sainte-Foy (Quebec). Service des Eaux de Surface.
V. D. Hoang, and B. Robert.
Canadian Journal of Civil Engineering, Vol 8, No 4, p 433-441, 1981. 4 Fig, 3 Tab, 5 Ref. English summary.

Descriptors: *Hydrologic models, *Lakes, *Forecasting, Prediction, Water levels, *Lake Memphremagog, *Quebec, Flood control, Snowmelt, Runoff, Watersheds, *Inflow forecasting.

Water inflow forecasts are being designed for some Quebec watersheds for the purposes of environmental protection and to fulfill international agreements. Accurate assessment of runoff during the spring thaw and periods of heavy rain was necessary for Lake Memphremagog near Magog, Quebec, in view of the low discharge capacity at the outlet of the lake and the obligation to regulate water levels. A hydrometeorologic model of the deterministic type, the SSARR (streamflow synthesis and reservoir regulation) model, was selected. This model makes it possible to calculate the snowmelt based on daily temperature and precipitation values, whereas the other possibility, the Ohio-Stanford model, requires a knowledge of numerous physical parameters requiring complex measurements. The SSARR model incorporates sub-models of the watershed, the river drainage, and the lake reservoir, plus a forecasting model. The resulting model was calibrated using data from the Black River for 1971-1973, then verified with data from 1974 and 1975. The error in the observed flow compared to the calculated flow was estimated using the criterion of volume, the point criterion, and the final criterion. Predictive application of this model in 1979 gave highly encouraging results, with an error of about 16%. Further improvements are desired to reduce the error to 10%, but the information already available will permit adequate flood warning for downstream residents plus systematic operation of the outlet dam. (Carroll-FRC)
W82-04459

REGIONAL HYDROLOGIC MODELS FOR CLIMATOLOGY: AN APPLICATION TO THREE WISCONSIN WATERSHEDS,
Wisconsin Univ.-Madison.
D. R. Clark.
PhD Thesis, May, 1981. 106 p, 19 Fig, 17 Tab, 35 Ref, Append. University Microfilms International, Ann Arbor, MI; Order No GAX81-17508.

Descriptors: *Watersheds, *Hydrologic models, *Seasonal variation, *Evapotranspiration, Runoff, Drainage, Recharge, Soil moisture retention, *Climatology, *Wisconsin.

Two hydrologic models are applied to three watersheds in south central Wisconsin over a thirty year period. Although in the same climatic region, the three watersheds have different hydrologic responses due to their different basin characteristics. The two models are designed for the study of seasonal interactions between external climatic factors and regional hydrologic responses. Input data consists of monthly rainfall, snowmelt, absorbed solar radiation, frost depth and an empirical vegetation seasonality index. Evapotranspiration is parameterized in terms of absorbed solar radiation, a vegetation seasonality index, and moisture storage. Parameterization of runoff and drainage between storages includes the effect of soil freeze and moisture storage. Model parameter values were obtained by calibration of model runoff to observed streamflow. Model storage levels were compared to water table observations in one watershed. Sensitivity of the calibrations was tested by a series of Monte-Carlo experiments using randomly perturbed input data, and by parameter sensitivity tests. The two storage model is found to simulate streamflow just as well as the three-storage model. Normal spring ground water recharge is reduced or absent when preceding fall precipitation fails to replenish summer soil moisture losses, or scant snowcover permits deep winter soil freeze. Major recharge episodes result from consecutive months of excessive precipitation or snowmelt, but not from an isolated high-input month. (Sinha-OEIS)

DIGITAL-MODEL SIMULATION OF THE TOPPENISH ALLUVIAL AQUIFER, YAKIMA INDIAN RESERVATION, WASHINGTON,
Geological Survey, Tacoma, WA. Water Resources Div.
E. L. Bolke, and J. A. Skrivan.
Geological Survey Open-File Report 81-425 (WRI), 1981. 34 p, 14 Fig, 2 Tab, 8 Ref.

Descriptors: *Computer models, *Aquifers, *Surface-groundwater relations, *Water use, Simulation analysis, Model studies, Water demand, Hydrologic budget, Irrigation, Streamflow, Wells, Water levels fluctuations, Groundwater movement, Hydraulic conductivity, *Washington, *Yakima Indian Reservation, Yakima River.

Increasing demands for irrigating additional lands and proposals to divert water from the Yakima River by water users downstream from the Yakima Indian Reservation have made an accounting of water availability important for present-day water management in the Toppenish Creek basin. A digital model was constructed and calibrated for the Toppenish alluvial aquifer to help fulfill this need. The average difference between observed and model-calculated aquifer heads was about 4 feet. Results of model analysis show that the net gain from the Yakima River to the aquifer is 90 cubic feet per second, and the net loss from the aquifer to Toppenish Creek is 137 cubic feet per second. Water-level declines of about 5 feet were calculated for an area near Toppenish in response to a hypothetical tenfold increase in 1974 pumping rates. (USGS)

A DIMENSIONLESS UNIT HYDROGRAPH FOR URBANIZING CATCHMENT AREAS,
Sir William Halcrow and Partners, London (England).
M. J. Hall.
Proceedings of the Institution of Civil Engineers, Part 2: Research and Theory, Vol 71, No 1, p 37-50, March, 1981. 3 Fig, 4 Tab, 28 Ref.

Descriptors: *Urbanization, *Hydrographs, *Streamflow forecasting, Land use, Rainfall-runoff relationships, Paving, Runoff, *Urban runoff, Excess rainfall, England.

A method for quantifying changes in flow regimes caused by urbanization was developed. Unit hydrographs corresponding to a common duration for catchments in different stages of urban growth were correlated with catchment characteristics such as degree of urban development. This procedure was used with data from several areas in England to derive a dimensionless one-hour unit hydrograph. The scaling parameter for the hydrograph was expressed as a function of the basin ratio and the percentage of impervious area. (Cassar-FRC)

FORECASTING CHANGES OF WATER RESOURCES IN LARGE RIVERS FOLLOWING LAND DRAINAGE,
Gosudarstvennyi Gidrologicheskii Inst., Leningrad (USSR).
S. M. Novkov, and J. S. Goncharova.
Hydrological Sciences Bulletin, Vol 26, No 4, p 393-398, December, 1981. 10 Ref.

Descriptors: *Hydrologic budgets, Evaporation, Swamps, *River basins, *Drainage effects, *Hydrologic models, *Land management, Groundwater depletion, Predictions, Marshes, Wetlands, Catchment areas, Runoff, Model studies, Simulation analysis, Mathematical studies, Drainage.

Methods for predicting the annual water balance of a large river basin after drainage are considered. The precipitation of the model situations was assumed to be constant and unaffected by drainage. Drainage in the improved basins caused the annual runoff to decrease groundwater and swamp water resources, leading to changes in evaporation patterns. Reductions in groundwater resources were calculated for each percent of the basin drained, based on experimental data on the hydrophysical properties of mineral soils and subsoils and peats. Using this method, reductions in groundwater were taken into account, while changes in runoff were predicted. Evaporation changes were calculated from the difference between the potential evaporation (maximum possible evaporation) from cultivated sections and that from undisturbed swamps. (Geiger-FRC)

2B. Precipitation

A PRELIMINARY STUDY OF COMPARATIVE MEASUREMENTS OF RAINFALL RATE USING THE DIFFERENTIAL REFLECTIVITY RADAR TECHNIQUE AND A RAINGAGE NETWORK,
Ohio State Univ. Columbus. Dept. of Electrical Engineering.
T. A. Seliga, V. N. Bringi, and H. H. Al-Khatib.
Journal of Applied Meteorology, Volume 20, No 11, p 1362-1368, November, 1981. 5 Fig, 3 Tab, 13 Ref.

Descriptors: *Remote sensing, *Radar, *Rainfall, Raingages, Rainfall distribution, *Rainfall rate, Mathematical studies, Rainstorms, Chicago, Illinois, Measuring instruments, Calibrations, Spatial distribution.

Areal measurements of rainfall rate obtained by the differential reflectivity Z-DR technique were compared with raingage measurements and conventional radar measurements for two 550 sq km areas in the Chicago region over time intervals of about 1 hr. Z-DR is defined as ten times the logarithm of the quotient of the reflectivity at horizontal polarization divided by the reflectivity at vertical polarization. A relativecalibration between horizontally and vertically polarized reflectivities was done by pointing the radar vertically and comparing reflectivity factors at orthogonal polarizations. On the test day rainfall occurred over a wide area and lasted for several hours. Excellent agreement between radar Z-DR and raingage measurements was found; the Z-DR results were considerably better than those from two Z-R (reflectivity-rainfall rate) relationships, one of which was calibrated with 20 minutes of gage measurements. The University of Chicago-Illinois State Water Survey radar used had slow polarization switching, and significant improvements in the differential reflectivity measurements would be obtained by pulse-to-pulse switching of polarization. Over one of the 550 sq km areas the Z-DR method measured 86%

LIBRARY U. OF ILL. URBANA CHAMPAIGN

of the rainfall recorded on 26 raingages during an observation period of 80 min, and over the other, 117% of the rainfall recorded on 27 raingages was obtained during a 40 min period. (Carroll-FRC)

DIFFERENCES BETWEEN SOME RADAR RAINFALL ESTIMATION PROCEDURES IN A HIGH RAIN RATE GRADIENT STORM,
Bureau of Reclamation, Denver, CO.
G. E. Klazura.
Journal of Applied Metorology, Vol 20, No 11, p 1376-1380, November, 1981. 1 Fig, 1 Tab, 8 Ref.

Descriptors: *Remote sensing, *Rainfall, *Rain gages, *Radar, Rainfall distribution, Rainfall intensity, Mathematical studies, Convective precipitation, Rainstorms, Montana, Calibrations, Spatial distributions.

Attempts have been made to achieve optimal estimates of precipitation by combining radar and raingage data, essentially using raingages to calibrate the radar measurements. One method of calibration is that of computing an adjusted radar-rainfall field by means of the G/R ratio (gage amount divided by the sum of radar-derived rainfall throughout a rainfall event). A study was conducted to examine how much the G/R ratios would vary in an actual high rainfall-rate gradient situation considering the location and size of the radar contributing area, computation of radar-estimated rainfall using maximum, average or integrated values, and radar reflectivity factor threshold for average and integrated values. Data examined were collected on a convective shower day, June 6, 1976 at Miles city, Montana. Differences exceeded a factor of 6 and 3 were observed for individual gages and for the mean of 17 gages, respectively. Conclusions were incompleted because of the limited data set analyzed and the absence of positive truth, i.e., knowledge of the location of the most representative radar bin. Withouth a comparative analysis it was impossible to know whether improvements in G/R values will produce better rainfall estimates. If wind information is available at each gage location it may be possible to make a reverse trajectory analysis to identify the most representative radar bin for each averaging time period. If isolation of the representative radar bin is not possible, it is probably best to use either the averaging or integrating method with a reflectivity factor threshold, allowing for precipitation drift and evaporation. (Carroll-FRC)

HYDROCLIMATOLOGICAL CHARACTERISTICS OF ISOLATED SEVERE RAINSTORMS,
Illinois State Water Survey, Urbana.
S. A. Changnon Jr., and J. L. Vogel.
Water Resources Research, Vol 17, No 6, p 1694-1700, December, 1981. 7 Fig, 3 Tab, 7 Ref.

Descriptors: *Rainfall intensity, *Weather forecasting, *Storms, Precipitation intensity, Flood forecasting, Flash floods, Local precipitation, *Illinois, Rainstorms, Rainfall distribution, Rain gages, Climatology.

Intense, very localized severe rainstorms were studied in Illinois, where four dense rain gage networks produced data from 32 storms in the warm season, May-September, 1955-1978. These storms, responsible for flash floods with resulting erosion and water pollution, generally last 3-12 hours, affect less than 1000 sq km, and have 1 to 4 hour rainfall totals in excess of 7.5 cm. About 40 such storms occur over Illinois (145,000 sq km) each warm season. The storm of July 30-31, 1979, over central Illinois is described in detail. The storm began at 1445 CDT and ended by 2100. Over 17.8 cm of rain fell, with the greatest intensity within 4 hours, at a station near Urbana. The core of this storm was extremely small. Only 8 sq km received a depth of 18 cm or more, and 960 sq km received 5 cm or more. The storm occurred in a maritime tropical air mass and was not associated with frontal activity. Prior to the start of the storm the surface dewpoint temperature was greater than normal (23-26 C), the atmosphere was unstable, precipitable water from the surface to 400 mb was greater than average (3.97 cm), and wind speeds increased with height from 7.7 mps at 850 mb to 12.9 mps at 500 mb. Three distinct precipitation systems with a total of nine rain cells moved over the region. Radar and satellite photos can be used to detect the development of localized intense rainstorms. Characteristics of this type of storms--stationary multicelled in nature with strong preference for afternoon development--are keys for detection and local flood warnings. (Cassar-FRC)

SECULAR CHANGES IN ANNUAL AND SEASONAL GREAT LAKES PRECIPITATION, 1854-1979, AND THEIR IMPLICATIONS FOR GREAT LAKES WATER RESOURCE STUDIES,
National Oceanic and Atmospheric Administration, Ann Arbor, MI. Great Lakes Environmental Research Lab. MI.
F. H. Quinn.
Water Resources Research, Vol 17, No 6, p 1619-1624, December, 1981. 5 Fig, 5 Tab, 12 Ref.

Descriptors: *Water level fluctuations, *Seasonal variation, *Water management, *Great Lakes, *Precipitation, Climatic data, Lakes, Lake shores, Erosion, Statistical analysis.

Two distinct precipitation regimes were identified by statistical analysis of annual precipitation data in the Great Lakes basin from 1854-1979. Since the late 1930's the precipitation regime has been relatively wet, with an increase in average annual precipitation of 50 mm per year, due primarily to greater amounts of spring and summer precipitation. A dry period existed from the mid- 1880's to about 1940. Prior to 1880 the sketchy records indicate that precipitation was similar to the present. Recorded levels of Michigan-Huron-Erie corresponded with the precipitation through the years of interest. In addition, annual flows of the Niagara River from 1860 to the present show above average flows before 1890 and after 1940, with below average flows in the interim years. This may mean that the present relatively wet conditions are the normal climate for the basin. If this persists, water managers must deal with problems such as poor performance of the current Great Lakes regulation plans, continuing erosion due to high lake levels, and revisions in water supply forecasting techniques to account for higher precipitation. THUNDERSTORM IN AGRICULTURE AND IN FOREST MANAGEMENT,
Science and Education Administration, Oxford, MS. Sedimentation Lab.
D. G. DeCoursey, W. L. Chameides, J. McQuigg, M. H. Frere, and A. D. Nicks.
In: Thunderstorms: A Social, Scientific, and Technological Documentary, Vol I, The Thunderstorm in Human Affairs, NOAA, September, 1981, p 85-112, 21 Fig, 1 Tab, 54 Ref.

Descriptors: *Thunerstorms, *Forest management, *Agriculture, Precipitation, *Water pollution, Nitrogen fixation, Lightning, Flooding, Soil erosion, Water pollution, Sediments, Hail, Nutrients, Pesticides, Channel erosion, Gully erosion, *Storm runoff, Sediment transport, Overland flow.

Precipitation can be divided into two general types: that associated with weak ascending air currents on a scale of about 1,000 km, and that associated with rapid overturning of a local air mass with large variability of air motion and precipitation on a scale of tens of kilometers. The showers and thunderstorms identified with the second type can be beneficial or harmful to agriculture. Beneficial effects of thunderstorms include: moisture for crop production; farm and ranch water supply; irrigation water supply; and nitrogen fixation by lightning. Harmful effects of thunderstorms can be grouped into four major areas: damage directly to rangeland and crops by hail, flooding, or wetting an air-dried product; erosion of cropland caused by excessive runoff rates; leaching of plant nutrients from the soil profile; polluting surface waters; flooding of cropland along major streams. Heavy rain, usually associated with thunder, produces large volumes of surface runoff, with resulting loss of soil and associated pollutants, including sediment, nutrients, and pesticides. Overbank flooding on a typical stream is estimated to occur once in 1 to 4 years. Quite often, flooded areas include the most productive soils planted with high-yield crops. Erosion of stream channels and gullies indirectly resulting from heavy rains is a major problem. (Moore-SRC)

CHEMICAL COMPOSITION OF MONSOON RAINWATER OVER BHOPAL, MADHYA PRADESH (INDIA) DURING 1977 AND 1978,
Indo-British Betwa Groundwater Project, Bhopal (India).
D. K. Das, G. K. Burman, and A. L. Kidwai.
Mausam, Vol 32, No 3, p 221-228, July, 1981. 5 Fig, 3 Tab, 17 Ref.

Descriptors: *Rain, *Chemical composition, *Monsoons, *India, Bicarbonates, Calcium, Salinity.

Monsoon rainwater samples collected at Bhopal, India, during June-August 1977 and April-September 1978 contained variable levels of chemical constituents. Bicarbonate and calcium were the predominant anion and cation, with concentration ranges of 2.4-32.0 (average 10.0) mg per liter and 0.6-12.0 (average 3.0) mg per liter, respectively. pH ranged from 6.0 to 7.2, average 6.2. EC varied from 15 to 80 micromhos per cm at 25 C. Concentration ranges of other constituents were as follows (in mg per liter): chloride, 0.9-9.4 (average 3.4); sulfate, 1.2-5.8 (average 3.2); nitrate, 0.12-0.88 (average 0.5); Mg, 0.16-4.3 (average 0.81); Na, 0.08-4.3 (average, 0.80); K, 0.01-1.2 (average 0.16); boron, 0.002-0.068; fluoride, 0.1; Fe, 0.01-0.08; and silica, 0.4-2.8. Ranges of trace metals were as follows (in ppb): Sr, 1-30; Zn, 10-76; Mn, 1-5; Cu, 1-8. No Li or Ni was detected. It is believed that most of the chemical constituents in the monsoon rainwater were from non-marine sources. (Cassar-FRC)

USEFULNESS OF MONTHLY RAINFALL NORMALS IN AGROCLIMATIC MAPPING,
Meteorological Office, Poona (India).
R. R. Kelkar.
Mausam, Vol 32, No 2, p 181-188, April, 1981. 7 Fig, 16 Ref.

Descriptors: *Rainfall distribution, *Mapping, *Planting management, Agriculture, *India, Crops, Planning, Seasonal variation, Meteorological data collection.

Several attempts to obtain rainfall data more appropriate than monthly rainfall data for agricultural planning in India are described. Most data and maps apply to the state of Maharashtra. The sowing rains concept is based on the dates of commencement of sowing rains (CSR), which are defined as a spell of at least 25 mm of rain in 7 days with 1 mm or more on any 5 of these 7 days. Raman applied this method to maps showing CSR dates for Maharashtra. Also indicated are standard deviation of CSR, average interval between CSR and next wet spell, and median CSR distribution. This information shows areas where likelihood of short growing seasons and necessity of second

sowings are high. Probability analysis indicates the probability of rainfall being adequate in a given week. India's total annual rainfall does not vary widely in spite of droughts and floods. Therefore the coefficient of variation has been used to indicate monthly rainfall patterns in stations throughout India. A simple method, an extension of the National Commission on Agriculture's mapping technique, involves only monthly normals of rainfall and number of rainy days. This accounts for large amounts of rainfall on isolated occasions when much water is lost as runoff. Maps prepared using this technique indicate optimum time of sowings, good locations for surface runoff ponds, places for early-maturing varieties, and sites for no karif planting but early rabi planting. STATISTICAL FORECASTING OF HEAVY RAIN AND FLOODS IN THE RIVER TEESTA,
Flood Meteorological Office (India).
A. Lahiri.
Mausam, Vol 32, No 1, p 41-44, January, 1981. 2 Fig, 7 Tab, 8 Ref.

Descriptors: *Rainfall distribution, *Synoptic analysis, *Flood forecasting, Weather forecasting, Forecasting, *Teesta River, *India, Monsoons, Rainfall-runoff relationships, Mountains, Precipitation.

Heavy rain producing synoptic systems were associated with intervals of average precipitation to produce quantitative precipitation forecasting in the 80% mountainous Teesta River catchment, India. The region is affected by six categories of heavy rain producing synoptic systems, classified according to the position of the low pressure areas or monsoons. The frequency distributions of floods occurring from precipitation amounts of 11-25, 26-50, and > 51 mm in the six categories range from 2 to 19, with a total of 46. Frequency distributions of heavy average areal precipitation for the same groups of precipitation amounts in the 5 months of the flood season are as follows: June, 113, July, 122, August, 105, September, 70, and October, 13. June, July, and August are the most flood prone months, partly because heavy rains are not evenly distributed. In September and October heavy rains are more evenly distributed. (Cassar-FRC)

EVIDENCE OF URBAN AND LAKE INFLUENCES ON PRECIPITATION IN THE CHICAGO AREA,
State Water Survey Div., Champaign.
S. A. Changnon, Jr.
Journal of Applied Meteorology, Vol 19, No 10, p 1137-1159, October, 1980. 17 Fig, 11 Tab, 20 Ref.

Descriptors: *Precipitation, *Urban areas, *Lakes, *Rainfall, Areal precipitation, *Environmental effects, Convective precipitation, Rainfall distribution, Storms, Illinois, *Chicago, St Louis, Missouri.

A study of summer precipitation conditions in the Chicago, Illinois, area sought to discern evidence of urban influences on precipitation processes and on rainfall magnitude by investigating the time and space characteristics of clouds, radar echoes, surface rainfall, and thunderstorms. Historical data for the period 1931 through 1977 anddata from new and special instruments operated during the period 1975 through 1978 were investigated to identify local and regional influences as suggested by precipitation time trends, the areal distribution of heavier rainstorms, thunderstorm frequencies, cloud distributions, radar echo characteristics, raincells, rainfall in discrete rain periods, and total rainfall. An area of 15 percent greater rainfall, which was considered largely a result of urban influences, was identified in central Chicago. Although the degree of change is less than that found in studies at St. Louis, possibly as a result of the inhibiting effects of the lake at Chicago, there was general agreement between these two studies with respect to the placement of the rain change, the synoptic weather conditions when rain changes occur, and the tendency for rain changes to exist in heavier rainfall conditions. Limited causative studies suggest an urban enhancement of convective clouds over Chicago and southern Lake Michigan during the later afternoon. Case studies of radar echo behavior showed that maximum echo intensification repeatedly occurred over the city and at higher elevations than in non-urban cells. (Carroll-FRC)

TESTS OF FRAZIL COLLECTOR LINES TO ASSIST ICE COVER FORMATION,
Cold Regions Research and Engineering Lab., Hanover, NH.
R. E. Perham.
Canadian Journal of Civil Engineering, Vol 8, No 4, p 442-448, December, 1981. 10 Fig, 1 Tab, 1 Ref.

Descriptors: *Frazil ice, *Ice cover, *Ice formation, Rivers, Water flow, Flow velocity, Line sets, Experimental data.

Laboratory and field tests were performed on frazil ice collector lines to discover methods of promoting solid ice cover formation in fast flowing, shallow river sections. Line sets were composed of nylon parachute cord, nylon twisted rope, nylon braided line, and a combination of nylon, steel, brass, and aluminum, with 1 to 40 lines and different line lengths and spacings. Laboratory tests using a refrigerated flume were conducted with flume depths of 2-22 cm and average flow velocities of 0.08-0.84 m per sec. The tests in small mountain rivers 33-50 cm deep had average flow velocities of 0.6-0.8 m per sec. In the flumes at -23 to -26 C, frazil ice collected rapidly on the test lines, typically reaching a diameter of 3.2 cm in 15 min. Density of the drained ice was 470 kg per cu m, and porosity was 49%. The best river test results were obtained from a set of 20 lines, 3.2 mm diameter, 4.9 m long at a spacing of 38 mm and placed parallel to the streamflow. An ice cover 0.9 m wide and 5 m long formed overnight at about -20 C in swift water, 0.7 m per sec. Ice covers formed either from frazil ice collecting on submerged line sets and then floating to the surface or on lines initially floating. Possible applications for frazil collectors are fringed ice booms, a reinforced ice cover for a power canal or shallow stream, and ice sheet anchors to stabilize large ice sheets. (Cassar-FRC)

CONVECTION PATTERNS IN A POND,
Washington Univ., Seattle. Dept. of Atmospheric Sciences.
K. B. Katsaros.
Bulletin of the American Meteorological Society, Vol 62, No 10, p 1446-1453, October, 1981. 5 Fig, 18 Ref.

Descriptors: *Convection, Stratification, *Thermal stratification, *Ponds, *Ice, Ice cover, Snow, Flow pattern, *Slush.

Unusual convection patterns were noted in snow-slush on a pond in Seattle, Washington, during January of 1980 and again during February of 1981. The patterns resemble a spoke-type convection discovered experimentally by Busse and Whitehead in 1974. The first reference to large-cell patterns on a pond was made in Surrey, England, in 1946. Similar findings were reported in 1958 concerning a pond in Darmstadt, Germany, with one or two open spots in the centers. The pond in current question is a shallow and seasonal one, drying up in the summer and filling from rains in the fall. No discernible inflow or outflow exists. Temperatures at the bottom of the pond were 1.5 to 2 degrees C, while the slush layer on top was at zero degrees C and 0.08 meter in thickness. Air temperature above the pond was about 0.5 degrees C. At the time the pictures were taken, the pond was stably stratified. (Baker-FRC)

ACID SNOW IN THE CANADIAN HIGH ARCTIC,
Department of Energy, Mines and Resources, Ottawa (Ontario). Polar Continental Shelf Project.
R. M. Koerner, and D. Fisher.
Nature (London), Vol 295, No 5845, p 137-140, January 14, 1982. 3 Fig, 1 Tab, 16 Ref.

Descriptors: *Snow, *Chemical analysis, Precipitation, Snow sampling, Arctic regions, *Air pollution effects, Environmental effects, *Acidity, Canada, *Ice, Arctic, Ellesmere Island.

Acid concentrations in ice from part of a 337 meter surface to bedrock core taken on northern Ellesmore Island are presented. The sample represents the past 5000 years and was compared with the significantly higher acid concentrations occurring in snow deposited over the past 25 years at the same location, showing seasonal variations in the concentrations which together constitute a significant trend of increasing acid levels over the past 25 years. The most highly acid snow is located at the snow surface when melt begins in May or June in the high Arctic. Unless this melt refreezes at the base of the snowpack, the first runoff in spring will be the most acid. Acid levels in high Arctic snow and their effects should be monitored, especially in areas where the lake fish form a source of Inuit income. Concentrations of sodium, calcium, potassium, and magnesium along with insoluble particulates were also maximum in the spring. (Baker-FRC)

Within-species competition between clumps of the grass Hilaria rigida was investigated using conventional plotless techniques and also by root excava-

LIBRARY U. OF I. - URBANA CHAMPAIGN

tions. Root distribution was determined and leaf water vapor conductance measured. Larger clumps were found further from a random point as well as separated from their nearest neighboring plants by greater distances than smaller clumps. Larger clumps had more ground area available for their roots. The larger space occupied by the larger clumps presumably reflected their preemption of ground water. On the smaller clumps of less than 10 culms, leaves had a three fold higher rate of transpiration per unit leaf area than had leaves on larger clumps, of over 200 culms. However, the larger clumps had nearly three times as much leaf area per unit ground area. Therefore the depth of water transpired daily did not depend on the size of the clump. Since the amount of carbon dioxide fixed per unit ground area also did not change with clump size, the pattern of small and large clumps may be quite persistent over time. (Baker-FRC)

BLANEY-CRIDDLE COEFFICIENTS FOR WESTERN TURF GRASSES,
Wyoming Univ., Laramie.
J. Borrelli, L. O. Pochop, W. R. Kneebone, I. L. Pepper, and R. E. Danielson.
Journal of the Irrigation and Drainage Division, Proceedings of the American Society of Civil Engineers, Vol 107, No IR4, p 333-341, December, 1981. 6 Tab, 15 Ref.

Descriptors: *Consumptive use, *Evapotranspiration, *Turf grasses, *Semiarid lands, *Water supply development, Evaporation, Transpiration, Grasses, Semiarid climates, Urban areas, Water requirements, Water supply, Vegetation effects, Mathematical studies.

Very little data exists on calculating the consumptive use of water by turf grass. Some data on turf grass evapotranspiration recorded from lysimeter studies over extended periods at various locations were used to calibrate a Soil Conservation Service (SCS) modification of the Blaney-Criddle technique of calculating evapotranspiration. Results obtained from the revised method should be useful in yielding fairly accurate estimates of city wide water requirements for turfed areas typical of the western United States for use in long range water supply evaluations. Data from these SCS calculations showed that warm season turf grasses should be used in warm regions because they consume considerably less water than other types. In transition areas with summer temperatures over 25 degrees, cool season grasses may undergo heat stress and suffer a decrease in evapotranspiration rates. (Geiger-FRC)

USE OF MODIFIED BLANEY AND CRIDDLE FORMULA FOR ESTIMATING WATER REQUIREMENTS,
Meteorological Office, Poona (India).
K. Subba Rao, and G. Yazdani.
Mausam, Vol 32, No 2, p 195-200, April, 1981. 1 Fig, 5 Tab, 9 Ref.

Descriptors: *Evapotranspiration, *Water requirements, Evaporation, *Irrigation requirements, *India, *Rice, *Sugarcane, Blaney and Criddle method, Crop growth stage coefficient.

Experimental values of the crop growth stage coefficient (Kc) were determined for paddy and sugarcane from lysimeter data recorded at four locations in India. Kc gradually increased with advancement of the crop season, reached a peak at about 65% of the growing season, and then declined. This seasonal variation was similar to potential evaporation. Kc values for sugarcane were 0.6-1.1 and for paddy, 0.5-11, 0.6-1.4, and 0.7-0.9 at 3 locations. Ratios of potential evapotranspiration to pan evaporation were 0.9-1.7 for paddy and 0.5-2.0 for sugarcane. The modified Blaney and Criddle method was used to compute evapotranspiration using Kc derived in this work. Differences from measured values for paddy ranged from -6.4 to 16.8 mm. Previous work, which probably used Kc unsuitable for these locations, obtained values differing from the observed values by -40.6 to +29.0. (Cassar-FRC)

MODELLING EVAPORATION FROM RESERVOIRS,
Salford Univ. (England). Dept. of Civil Engineering.
B. Henderson-Sellers.
Hydrological Sciences Bulletin, Vol 26, No 4, p 363-367, December, 1981. 2 Fig, 1 Tab, 9 Ref.

Descriptors: *Mathematical models, *Reservoirs, *Water temperature, *Numerical analysis, *Reservoir evaporation, Lakes, Water management, Thermal stratification, Evaporation, Seasonal variation, Energy loss, Evaporation rate, Lake evaporation.

The greater thermal capacity of large reservoirs often delays the response of water temperature to changes in insolation and air temperature, offsetting the usual patterns of increased evaporation in the summer. A finite differences numerical model for predicting water temperature in the vertical dimension in freshwater reservoirs is described that is based on the annual variation of evaporation. The model is applicable to both small and large lakes, and the seasonal change in peak evaporation from summer (in small lakes) to winter (in large lakes) is satisfactorily simulated. Some differences in actual and model conditions may be observed, especially in March and August, due to the large spatial averaging inherent in both observations and calculations. In areas where water supplies are short, accurate calculations of evaporation rates may be vital to the planning of water management strategies. (Geiger-FRC)

Descriptors: *Streamflow, *Snowmelt, *Elevation, *Prediction, *Drainage area, *Alpine regions, Overland flow, Air temperature, Evapotranspiration, Altitude, Flood peak, Precipitation, Catchment areas, Runoff, Hydrologic data, Data collections, Orography, Vermont, New Hampshire.

Elevations in Vermont and New Hampshire are generally very high, with many mountain peaks exceeding 1200 m in height. As elevation increases, so does the mean annual and mean monthly precipitation, snow depth, and snow water equivalents, while mean monthly temperatures decreases. Temperature from National Weather Service networks may be used in conjunction with other data to illustrate how potential evapotranspiration fluctuares with elevation. These combined parameters exert strong elevational increases in mean annual streamflow and cause both short term and annual streamflow variability to decrease with the mean elevation of the drainage basin. As mean basin elevation increases above 340 m, low flows for a given exceedance probability show marked increases. For a given return period, flood peaks are also enhanced with increases in mean basin elevation. Although slope and aspect influence the timing of snowmelt runoff, these values exert little effect on hydrology. Usually elevation can be used as the single independent variable for predicting streamflow parameters. (Geiger-FRC)

CONFORMAL MAPPING FOR CHANNEL JUNCTION FLOW,
Malviya Regional Engineering Coll. Jaipur (India), Dept. of Civil Engineering.
P. N. Modi, P. D. Ariel, and M. M. Dandekar.
Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 107, No HY12, p 1713-1733, December, 1981. 7 Fig, 4 Tab, 2 Ref.

Descriptors: *Channel flow, *Flow characteristics, Streamflow, Hydraulics, Conformal mapping, Mapping, Open-channel flow, Stagnant water, Free-streamline theory, Mapping, *Channel junction flow.

Analysis of flow behavior at channel junctions where two streams combine to form a third is extended to cases with any junction angle and different bed widths. The solution was obtained with the aid of conformal mapping. For small values of the discharge ratio (discharge in channel 2 less than in channel 1) the stagnation point is along the channel 2 boundary closest to channel 1. In the opposite case, greater discharge in channel 1, the stagnation point coincides with the upstream corner at the junction point of the 2 channels. Relationships are developed for the location of the stagnation point with respect to junction angle and the ratio of bed widths of the two channels. For different locations of the stagnation points in the channel junctions, the solutions of the equation for the free-streamline are presented in dimensionless form. The location of the zone of stagnant fluid between the free-streamline and the channel boundary changes with changes in junction angle and as the stagnation point shifts from one channel to the other. ESTIMATION OF EXTREME LOW FLOWS FOR PUMPED STORAGE RESERVOIR DESIGN,
Newcastle upon Tyne Univ., (England). Dept. of Engineering Mathematics.
A. V. Metcalfe, and J. A. Mawdsley.
Water Resources Research, Vol 17, No 6, p 1715-1721, December, 1981. 7 Fig, 5 Tab, 11 Ref.

Descriptors: *Reservoir design, *Drought, *Low flow, River flow, *Flow augmentation, Poaka Beck reservoir, Crake River, *United Kingdom, Reservoir storage, Pumped storage, Minimum flow, Water transfer.

A model was developed for estimating extreme low flows with a certain probability of nonexceedance for reservoirs where natural inflow from a river is supplemented by pumping from an adjacent river. The method is based on the joint probability distribution of an extreme value distribution and a truncated extreme value distribution. The

estimates of the probabilities of given low flows are made using integrals which are evaluated numerically for a range of low flows and maximum daily pumping rates. Results obtained by applying the derived density function to 25 years of data from the Poaka Beck reservoir and the River Crake in northwest United Kingdom are given for a 3-month drought. This detailed model has several advantages: effects of varying parameters can be studied, flow sequence simulation is not necessary if a suitable distribution for pumped flows can be hypothesized, and the distributional models suggested for the low flows of the two streams are easier to justify than any other particular choice of distribution. RECONSTRUCTED STREAM FLOW FOR THE SALT AND VERDE RIVERS FROM TREE-RING DATA,
Arizona Univ., Tucson. Lab. of Tree-Ring Research.
L. P. Smith, and C. W. Stockton.
Water Resources Bulletin, Vol 17, No 6, p 939-947, December, 1981. 6 Fig, 5 Tab, 20 Ref.

Descriptors: Floods, Droughts, *Dating, *Streamflow, *Salt River, *Verde River, *Arizona, Trees, History, Flood peak, Precipitation, Planning, Water supply, Tree rings technique.

Tree ring data were used to extend streamflow records of the Salt and Verde Rivers, Arizona, back to 1580 A.D. The reconstruction of streamflows indicates that the available gaged records dating back to 1889 contain an above average number of high seasonal and annual flows when compared with the 400 year period. Peak flows may be similarly biased, making designs based on historical records of peak flow conservative. The average frequency of occurrence of annual and seasonal discharges associated with the peak flows has remained constant over the 400 year mean. Therefore, water supplies estimated using the historical means may be overestimated. Several long periods of low annual discharge, more severe than in the 1890 to present period, occurred on the average of every 22 years during the reconstructed period. In the Salt River Basin 1905-1920 was the wettest period in the 400 year period. A severe 5 year drought ended in 1670. Another low flow period was 1728-1739, during which average annual discharge was only 43% of the 400 year mean. The Verde River basin had high flows in the early 1900's and low flows at the turn of the century. The most severe drought was in the mid-1770's to mid-1780's. A possible low flow period, based on only 1 tree ring series, was 1580-1620. In general low and high flows in the Verde River coincided with those in the Salt River. (Cassar-FRC)

COMPARISON OF TWO AUTOREGRESSIVE MODELS FOR MONTHLY STREAM FLOW GENERATION,
Asian Inst. of Tech., Bangkok (Thailand).
H. N. Phien, and M. A. Khan.
Water Resources Bulletin, Vol 17, No 6, p 1035-1041, December, 1981. 8 Tab, 28 Ref.

Descriptors: *Streamflow, *Stochastic hydrology, Model studies, Reservoir storage, Thomas-Fiering model, Spolia-Chandler model, *Comparison studies, Laos, Thailand, Cambodia.

Two closely-related autoregression models for monthly streamflow generation were compared by theoretical consideration and practical applications to flow data from stations in Laos, Thailand, and Cambodia. The Thomas-Fiering model (1962) was superior to the Spolia-Chandler model (1974). The latter model is a reduced parameter modification of the Thomas-Fiering model. Errors in the reproduction of the correlation coefficient and skewness coefficient by the Thomas-Fiering model occurred during months when parameters are nearly zero. This is considered a remediable situation. The gamma random generator produced better results than the lognormal random generator in most cases. (Cassar-FRC)

WATER RESOURCES INVENTORY OF CONNECTICUT, PART 7, UPPER CONNECTICUT RIVER BASIN,
Geological Survey, Hartford, CT. Water Resources Div.
R. B. Ryder, M. P. Thomas, and L. A. Weiss.
Connecticut Water Resources Bulletin No 24, 1981. 78 p, 41 Fig, 23 Tab, 76 Ref.

Descriptors: *Groundwater, *Surface water, *Water quality, *Hydrologic data, Hydrologic cycle, Aquifers, Aquifer characteristics, Wells, Water supply, Streamflow, Sediment transport, Precipitation, Runoff, Chemical analysis, Maps, *Connecticut, *Upper Connecticut River basin.

The 508 square-mile upper Connecticut River basin during the 1931-60 period received an average of 44 inches of precipitation per year; evapotranspiration averaged 22.2 inches per year while inflow from streams was approximately 4,060 billion gallons per year. Flow out of the basin in the Connecticut River at Portland, Conn., averaged 4,230 billion gallons per year. In 1968, freshwater use was estimated at 108,547 million gallons, a small fraction of the total available. Ground-water sources in the basin yield from several million gallons per day at large well fields to 1 gallon per minute from single wells. Stratified-drift aquifers are the most productive and individual well yields of 100 gallons per minute or more are common. Bedrock aquifers that underlie the basin generally yield a few gallons a minute and are adequate sources for domestic supply. Surface-water samples collected at 25 sites in the area had median dissolved-solids concentrations of 113 milligrams per liter at high flow and 148 milligrams per liter at low flow. Ground-water samples from 164 wells had dissolved-solids concentrations that ranged from 52 to 2,060 milligrams per liter. High concentrations of iron, manganese, sulfate, sodium, and hardness cause ground-water quality problems in parts of the area. (USGS)

Descriptors: *Streamflow, *Water quality, *Precipitation, *Flow characteristics, Low flow, Flow duration, Fluvial sediments, Sediment discharge, *Kansas, Soldier Creek basin, Flood frequency, Comparison studies.

Hydrologic data from Soldier Creek basin, northeastern Kansas, were compared with relations from statewide data. The quantity and quality of streamflow were affected mostly by soils, slopes, and land use. Average annual precipitation during the study (1964-76) was 35.12 inches, or 2.3 percent greater than the long-term (1929-76) average. The average streamflow in Soldier Creek at Topeka was 23 percent greater than the long-term average. In general, frequency curves of annual peak discharges compared poorly with curves from statewide relations due to the absence of extremely low peaks during the short period. A comparison of low-flow frequency for drainage areas of more than 100 square miles suggests that reasonable results may be obtained by extrapolating the statewide relations to small basins. Comparisons of flow-duration curves confirms the extrapolation for basins of less than 100 square miles, although the percentage duration of mean flow is variable. Water surveys showed that calcium, bicarbonate, and sulfate were the predominant ions and dissolved solids were derived mostly from limestones and shales. Suspended sediment at gaged sites ranged from 9.84 to 848 tons per days; yield per unit area increased significantly between two sites due to changes in slopes and land use. (USGS)

DISASTER BY FLOOD,
National Oceanic and Atmospheric Administration, Boulder. Environmental Research Labs.
L. R. Hoxit, H. S. Lieb, C. F. Chappell, and H. M. Mogil.
In: Thunderstorms: A Social, Scientific, and Technological Documentary, Vol I, The Thunderstorm in Human Affairs, NOAA, September, 1981. p 23-45, 15 Fig, 27 Ref.

Descriptors: *Thunderstorms, *Flash floods, Precipitation, Flood forecasting, *Flood damage, Disasters, Flooding, Rainfall distribution, Warning systems, Canyons, *United States.

During the 1970's flash floods were the leading cause of death and destruction from weather-related causes; they have devastated parts of nearly every state. More than 15,000 communities and recreational areas have been identified as vulnerable to flash floods. Increased use of mountainous areas for recreation and canyons for home building has greatly increased the potential for disaster. The Big Thompson Canyon flash flood of 1976 is an example of the meteorological processes, the problems of warning and preparedness, and the human response to floods. Intense thunderstorms produced up to 12 inches of localized rainfall within a few hours over the rugged Big Thompson River drainage in north-central Colorado. The normally placid river received great quantities of water from several tributaries. Near Drake, the flow on the river just before the rain began was 137 cfs; the peak flow was 31,200 cfs. Only a few hours separated the onset of heavy rain from the flood crest passing the canyon mouth. The phenomenal local episode was appreciated only after it was under way, and many people either disregarded warnings or received no warning. The flash flood that swept through the canyon and onto the plains resulted in 139 casualties and property damage estimated at $35 million. The toll taken by flash floods in the future will be determined by the nature and density of settlements, the quality of flood control measures, the systems used for acquiring and interpreting meteorological observations, forecast and

THE DISASTROUS SOUTHERN CALIFORNIA AND CENTRAL ARIZONA FLOODS, FLASH FLOODS, AND MUDSLIDES OF FEBRUARY 1980.
National Weather Service, Silver Spring, MD.
Natural Disaster Survey Report NWS-81-1, March, 1981. 128 p, 28 Fig, 3 Tab, 7 Append.

Descriptors: *Floods, *Flash floods, Flood forecasting, *Mudflows, Rainfall distribution, Weather forecasting, Warning systems, *Flood damage, *California, *Arizona.

For 9 days during mid-February 1980, the southwestern U.S. was battered by a series of heavy rainstorms. Over the period, 5 inches or more of rain fell over most of Southern California's coastal valleys, and some mountain areas received over 25 inches. Rainfall amounts in Central Arizona ranged from 1 to over 16 inches. The large rainfall amounts produced floods and flash floods in many areas, and mudslides were a major problem in Southern California. Overall, the NOAA warning systems worked well in both California and Arizona. The Los Angeles Weather Service Forecast Office (WSFO) issued watches, warnings, and statements well in advance of flooding, flash flooding, and mudslides. The Phoenix WSFO also issued timely flood/flash flood watches, warnings and statements. All indications are that the NOAA services contributed significantly to reducing property losses and probably deaths. Nevertheless, 21 people died as a direct result of flooding, flash flooding, and mudslides; and total property damage in the two states topped $400 million. Part of these losses might have been prevented if, in some cases, more effective action had been taken on the part of the public. One factor that apparently contributed to citizen inaction during this disaster was the inability to give a more precise description of the rainfall distribution in the warning statements. D. R. Archer.
Proceedings of the Institution of Civil Engineers, Part 2: Research and Theory, Vol 71, No 4, p 1023-1035, December, 1981. 7 Fig, 2 Tab, 3 Ref.

Descriptors: *Flood forecasting, Risks, *Seasonal variation, *Flood frequency, *England, Rainfall-runoff relationships, Soil water, Storm water, Streamflow forecasting.

A method for seasonal flood analysis is presented. It is based on the percentage of the annual number of floods above a given return period occurring in each month. Variations in seasonal regime are identified for stations in northeast England. These are related to controlling factors of storm rainfall and catchment wetness. A graph depicts the relationship between construction period/design life, return period, and the risk of flood occurrence. A table gives the percentage of annual number of flood events above a given return period occurring each month in three regions. This method can determine the seasonal flood risks to crops grown on a flood plain or to construction projects such as bridges, outfalls, and piers. (Cassar-FRC)

SEVERE SNOWMELT RUNOFF IN NORTHEAST ENGLAND AND ITS IMPLICATIONS,
Northumbrian Water Authority, Gosforth (England).
D. R. Archer.
Proceedings of the Institution of Civil Engineers, Part 2: Research and Theory, Vol 71, No 4, p 1049-1060, December, 1981. 4 Fig, 2 Tab, 19 Ref.

Descriptors: *Flood forecasting, *Snowmelt, *Runoff rates, Forecasting, Snow density, Snow depth, Melting, Streamflow forecasting, *England.

Measured snowmelt runoff rates in northeast Britain were considerably higher than those obtained from meteorological data. Analysis of snowmelt rates in 1978-97 confirmed earlier observations of runoff rates. The differences in rates were attributed to limitations in data on which the meteorological conclusions were based. No deep snowpacks were included in the estimates of water equivalent depletion. Rates of depth depletion do not directly indicate melt or yield. Densities of snowpacks in the uplands were also much higher than in the lowlands because of higher windspeeds, greater compaction due to deeper snow, and lower temperatures. These discrepancies can cause underestimates of probable maximum floods. (Cassar-FRC)

WATER QUALITY MONITORING - IDENTIFICATION OF RESIDENCE/TRAVELLING TIMES FROM HYDROLOGICAL AND WATER QUALITY INFORMATION,
Karlsruhe Univ. (Germany, F.R.).
G. Troubounis, H. H. Hahn, and B. Eppler.
Water Science and Technology, Vol 13, No 11/12, p 677-682, 1981. 2 Fig, 1 Tab, 5 Ref.

Descriptors: *Water quality, *Monitoring, Water pollution control, Hydrologic data, Rivers, Data collections, Data acquisition, Detection times, Detention time, Streamflow.

The corresponding residence or travelling time between monitored river cross sections is a necessary piece of information in conceiving a river quality monitoring program. This traveling or transit time is a function of the discharge rate of the river itself. The problems encountered in residence/traveling time determinations are discussed. Two methods are described which are more compatible with water quality considerations than the well known hydraulic computations: the use of iso-concentration graphs based on data for concentration changes of conservative water constituents, and time series analysis methods. Comparing the computed flow and traveling times between predetermined cross-sections, one finds significant differences between hydraulically computed data and those determined on the basis of water quality measurements. It is concluded that if automatic sampling or quasi- continuous analyses exist, then such data will form a sufficient basis for the determination of residence and traveling times in free flowing as well as impounded rivers. If periodic variations or oscillations in the quality of a river exist, then such quasi-continuous or continuous measurements on concentration changes of conservative substances can be used for a detention time determination on the basis of iso-concentration diagrams. If no periodic fluctuation in the concentration of conservative water constituents can be observed, but non-conservative substances are available, then the method using the cross-correlation function should be employed. THE FUTURE OF FLOOD ESTIMATION AND THE FLOOD STUDIES REPORT,
Northumbrian Water Authority, Gosforth (England).
P. Johnson.
Proceedings of the Institution of Civil Engineers. Part I. Design and Construction, Vol 70, No 3, p 833-843, 1981. 1 Tab.

Descriptors: *Flood flow, *Flood plain management, *Spillway capacity, *Rainfall, *Snowmelt, Floof forecasting, Flood-control storage, Floods, Data collections, Urban areas, Catchment areas, Runoff, Reservoirs, *United Kingdom.

The proceedings of the 1975 conference, The Flood Studies Report (FSR) held by the Hydraulics and Public Health Engineering Board of the Institution of Civil Engineers, are summarized in the committee chairman's report. Priority tasks to improve upon and extend the FSR are mainly ones of better mapping of flood boundaries, finding the adequacy of urban catchment, and estimating more accurately the trends and cycles of floods. Several priority tasks for updating the FSR will require more sophisticated and broader data base analyses. The REGIME concept for relating discharge to river channel cross-sectional areas and other features should be studied for application to the FSR. The URBAN program was adopted to aid in estimating flood discharges in or as a result of urban areas. Radar is suggested for more accurate data collections on rainfall. Information on snowmelt also needs more development. Plans were made to survey all major spillways in the British Isles and to examine wind velocities and directions of storms causing flood inflow. Recommendations to expand data on reservoirs in an engineering guide were also made. Extrapolation of FSR methods for use overseas and training in the proper understanding of the report are considered. (Geiger-FRC)

RESISTANCE EQUATION FOR LARGE-SCALE ROUGHNESS,
Institute of Hydrology, Wallingford (England).
J. C. Bathurst, R. M. Li, and D. B. Simons.
Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 107, No HY12, p 1593-1613, December, 1981. 11 Fig, 8 Tab, 21 Ref.

Descriptors: *Channel flow, *Flow resistance, *Hydraulic roughness, Flumes, Reynolds number, Rocks, Roughness coefficient, Froude number, Channel morphology, Resistance, *River beds, Bed material, Particle size, Mountain streams.

Flow in channels with large-scale roughness, such as boulder-bed channels increasingly being used in developing mountainous areas, was investigated in a steep stream flume. Bed material was of five different sizes, from 0.5 to 2.5 inches. A flow resistance equation was developed for this situation, in which the ratio of flow depth to mean element height was less than 4. The flow resistance in large-scale roughness depended on the form drag of the elements and their deposition in the channel. The relevant processes of flow were described as functions of Reynolds number, Froude number, roughness geometry, and channel geometry. Values predicted by this equation and by other workers for the Upper River Tees, United Kingdom, were compared with observed values. Agreement was generally good, but further refinement is necessary to account for variations in channel width and element shape. (Cassar-FRC)

A GROUND WATER RESOURCES STUDY OF A PACIFIC OCEAN ATOLL--TARAWA, GILBERT ISLANDS,
Birmingham Univ. (England). Dept. of Geological Sciences.
J. W. Lloyd, J. C. Miles, G. R. Chessman, and S. F. Bugg.
Water Resources Bulletin, Vol 16, No 4, p 646-653, August, 1980. 7 Fig, 2 Tab, 24 Ref.

Descriptors: *Groundwater potential, *Resistivity, *Atolls, Groundwater availability, Groundwater management, *Tarawa, *Gilbert Islands, Water supply, Drought, Aquifers, Lenses, Islands.

Groundwater resources were investigated in Tarawa, Gilbert Islands, typical of thousands of small atolls in the Pacific Ocean. Surface resistivity

measurements were combined with an electrical conductivity survey of well waters to establish the size and shape of fresh water lenses. Most wells in this atoll intercept only the top edge of the lens. Although precipitation is the controlling factor for groundwater recharge input, there is a 15% interception loss. Steady state conditions were not appropriate for modeling water resources in this atoll because long periods occur during which there is no recharge. Therefore nonsteady digital modeling methods were used to analyze the groundwater resources in the largest 4 of the 8 atolls in the Tara group. Results of the study showed that the 4 main lenses can supply water adequately for a 2% drought of 2-year duration. To prevent saline water intrusion, water should not be abstracted during the second year of a drought. Once a lens has been overabstracted, it may not recover. Increasing populations in these islands, the susceptibility of lens resources to drought, and the expense and difficulty of obtaining alternate intermittent water supplies are problems common to many Pacific atolls. (Cassar-FRC)

DELAYED DRAINAGE IN A STREAM-AQUIFER SYSTEM,
Arizona Univ., Tucson. Dept. of Hydrology and Water Resources.
S. P. Neuman.
Journal of the Irrigation and Drainage Division, Proceedings of the American Society of Civil Engineers, Vol 107, No IR4, p 407-410, December, 1981. 1 Fig, 7 Ref.

Descriptors: *Groundwater movement, *Subsurface drainage, *Mathematical models, *Drainage wells, *Unconfined aquifers, Aquifers, Drainage, Model studies, Hydrologic models, Mathematical studies, Water table, Mathematical equations, Flow patterns, Fully penetrating wells, Streams.

An explanation of Higgins' results for nonsteady flow from an unconfined aquifer into a fully penetrating stream in which the water level fluctuates in a prescribed pattern was developed which does not account for unsaturated flow. The proposed theory is similar to that of Higgins, except that the aquifer material is assumed to be uniformly elastic and the water compressible, and the aquifer itself is assumed to be anisotropic. The new theory is based on the concept of delayed drainage as applied to the problem of unconfined flow to a well. At small values of time, the water table drawdowns observed experimentally by Higgins exceeded those predicted by his theory, while at large values of time, some of the water table drawdowns observed by Higgins were less than those predicted by his theory. A simple explanation of how this situation occurs and equations to remedy this problem are presented. (Geiger-FRC)

THE SEEPAGE FLOW THROUGH A FREE BOUNDARY AQUIFER INTO A RIVER,
Reading Univ. (England). Dept. of Mathematics.
J. O'Shea, and M. J. Baines.
Hydrological Sciences Bulletin, Vol 26, No 4, p 415-411, December, 1981. 3 Fig, 2 Tab, 5 Ref.

Descriptors: *Groundwater movement, *Mathematical models, *Numerical analysis, Model studies, Hydrologic models, Aquifers, Mathematical studies, Mathematical equations, Rivers, *Influent streams.

A model of groundwater flow from an aquifer beneath a river into the river channel is presented in order to determine the discharge q into the river for different values of the boundary data, namely at the river boundary and at the outer edge of the aquifer. Information from this model may be applied for calculating the total water conten in a river or the inflow conditions when modeling water systems. The solution procedure for solving Laplace's equation utilizes a variational inequality, which yields a numerical approximation solution using finite differences. The discharge parameter q is determined from Neumann boundary conditions and iterations on q using a compatibility condition obtained by the discretizing of discharge equations. (Geiger-FRC)

HYDROLOGIC EFFECTS FROM CHANGES IN GROUND WATER PUMPAGE,
International Engineering Co., Incorp., San Francisco, CA.
M. V. Damm.
Water Resources Bulletin, Vol 16, No 5, p 907-913, October, 1980. 11 Fig, 2 Tab, 8 Ref.

Descriptors: *Groundwater, *Pumpage, Aquifers, Recharge, River basins, Simulation, *Groundwater recharge, Model studies, *Hydrologic budget, Nebraska.

The purpose of this paper is to explore the hydrologic effects of implementing an allocation scheme in an area where groundwater pumpage provides a substantial portion of the applied water. In general a reduction of pumped groundwater applied at the surface will result in less recharge to the groundwater body. Recharge will decrease in an amount approximately equal to the decrease in pumpage, as long as the water pumped is in excess of actual water needs. Simulation of a stream-aquifer system in Nebraska was undertaken to determine estimates of the effects of controls on groundwater withdrawals. Due to uncertainties in the calibration processes and projections of various types of data and to simplifications employed in the models, the results of the simulation most likely include some error. The relatively small savings from reductions in pumpage result primarily from recirculation effects. Differences between groundwater contributions to stream flow were small for all simulations examined. These contributions decreased with time and increased pumpage amounts. base flow rates at the end of the simulation were about 25% of those at the beginning. (Baker-FRC)

A NUMERICAL LINKED MODEL FOR THE PREDICTION OF THE DECLINE OF GROUNDWATER MOUNDS DEVELOPED UNDER RECHARGE,
Colorado State Univ., Fort Collins. Dept. of Civil Engineering.
H. A. Kashkuli.
PhD Thesis, July, 1981. 159 p, 21 Fig, 7 Tab, 59 Ref, 3 Append. University Microfilms International, Ann Arbor, MI; Order No GAX81-26436.

Descriptors: *Model studies, *Mathematical models, *Groundwater recharge, Groundwater movement, Saturated flow, Water table, *Groundwater mounds.

A model is developed to couple the approximate solution of one-dimensional vertical partially saturated flow to the two-dimensional saturated horizontal flow. The linked model is used to predict the decline of a groundwater mound developed under recharge areas. It consists of linking beneath the recharge area one-dimensional vertical unsaturated columns to a two-dimensional areal saturated flow model. Besides the Dupuit-Forchheimer assumptions in the saturated flow, it is further assumed that the partially saturated flow is vertical. The solution of the equation governing the partially saturated flow above the water table determined the recharge and storage information needed for the solution of the saturated flow equation. The model simulates the lateral unsaturated flow by an equivalent permeable height and uses an equivalent saturated height to account for a changing specific yield. The model was verified by comparing the results for a certain problem to those predicted by a rigorous model. A field size problem of strip recharge was simulated and solved. It was found that for this particular problem the water table decline rate is considerably faster if the traditional approach of excluding the unsaturated flow region is employed. In this model both Su-Brooks and Brooks-Corey methods for determining soil parameters can be used. (Sinha-OEIS)

The Cape Cod aquifer system was simulated with three-dimensional finite-difference ground-water-flow models. Five areas were modeled to provide tools which can be used to help predict the hydrologic impacts of regional water development and disposal schemes. Model boundaries were selected to represent the natural hydrologic boundaries of the aquifer. The boundary between fresh and saline ground water is treated as an interface of no dispersion, and the saline-water zone is treated as being non-flowing. Comparisons of calculated and observed head values, position of the freshwater and saline-water boundary, and ground-water-discharge rates at locations where data are available indicate that the simulated ground-water reservoirs generally agree with the field conditions and the models can be used for predictive studies. Descriptors: *Computer models, *Groundwater, *Aquifer systems, *Water management, Geohydrology, *Groundwater movement, Observation wells, Water level, Hydraulic conductivity, Available water, *Mississippi, *Lee County, Eutaw-McShan aquifer, Gordo aquifer.

A two-dimensional ground-water flow model of the Eutaw-McShan and Gordo aquifers in the area of Lee County, Miss., was successfully calibrated and verified using data from six long-term observation wells and two intensive studies of areal water levels. The water levels computed by the model were found to be most sensitive to changes in simulated aquifer hydraulic conductivity and to changes in head in the overlying Coffee Sand aquifer. The two-dimensional model performed reasonably well in simulating the aquifer system except possibly in southern Lee County and southward where a clay bed at the top of the Gordo Formation partially isolated the Gordo from the overlying Eutaw-McShan aquifer. The verified model was used to determine theoretical aquifer response to increased ground-water withdrawal to the year 2000. Two estimated rates of increase and five possible well field locations were examined. (USGS)

CARBONATE GEOCHEMISTRY OF VADOSE WATER RECHARGING LIMESTONE AQUIFERS,
Kentucky Univ., Lexington. Dept. of Geology.
J. Thrailkill, and T. L. Robl.
Journal of Hydrology, Vol 54, No 1-3, p 195-208, December, 1981. 4 Fig, 3 Tab, 20 Ref. OWRT-A-009-KY.

Descriptors: *Geochemistry, *Vadose water, *Groundwater recharge, Carbonates, Aquifers, Flow, Seepage, Caves, *Limestone aquifers.

An investigation of the carbonate equilibrium of water which is transiting the vadose zone in Kentucky caves included repeated sampling at the same sites to examine possible seasonal variations. Also, measurements were made of discharge at the sources, and the pH was determined as soon as possible after the water entered the cave environment. Furthermore, the carbonate chemistry of the soil waters overlying at least some of the sites was investigated. An apparent chemical distinction could be made between vadose flows and vadose seepage, with the vadose flows being originally more undersaturated with respect to calcite. Calcite is actively dissolved as water passes through the vadose zone. Two types of vadose seepage were identified: low-Ca vadose seepage and high-Ca vadose seepage. High-Ca vadose seepage is probably the most abundant source of recharge to limestone aquifers which are not overlain by other lithologies. (Small-FRC)

THEORY FOR AQUIFER TEST ANALYSIS IN FRACTURED ROCK UNDER LINEAR (NONRADIAL) FLOW CONDITIONS,
Water Futures, Albuquerque, NM.
D. N. Jenkins, and J. K. Prentice.
Ground Water, Vol 20, No 1, p 12-21, 1982. 11 Fig, 13 Ref.

Descriptors: *Mathematical studies, *Aquifers, *Groundwater movement, *Pump wells, Mathematical equations, *Geologic fractures, Drawdown, Permeability, Fracture permeability, Flow pattern, Graphical methods.

If a well penetrates a geologic fracture with a permeability much greater than that of the surrounding aquifer, then the flow of groundwater in a fractured rock aquifer may be linear toward a natural production surface rather than radial toward a pumping well. Such linear flow has been discovered in fractured rock aquifers in three distinct areas of New Mexico. Similar aquifers were identified from aquifer test data in Mendocino and Placer Counties in California. Conventional methods of aquifer analysis were deemed inadequate due to curvilinear test data on semi-log plots and straight line data on log-log plots. Mathematical methods of fitting straight lines to arithmetic plots of pumped well and observation well data showed that the flow in the vicinity of the test well was linear. Flow lines in a linear system are parallel, and drawdown is a function of the perpendicular distance from the extended well. (Geiger-FRC)

IRRIGATION, CROP YIELD AND DRAINAGE AT THE VAALHARTS IRRIGATION SCHEME: 3. THE INFLUENCE OF SALINIZATION ABOVE A SHALLOW GROUND WATER TABLE ON THE YIELD OF WHEAT AND OTHER CROPS (IN AFRIKAANS),
Navorsingsinstituut vir Grond en Besproeiing, Pretoria (South Africa).
A. Streutker, N. Van Vliet, and H. W. Molenaar.
Water SA, Vol 7, No 4, p 255-264, October, 1981. 6 Fig, 7 Tab, 13 Ref.

Descriptors: *Water table rise, *Irrigation effects, *Saline soils, Crop yield, Drainage, Conductivity, Water pollution effects, Soil water, *Vaalharts Irrigation Project, *South Africa, Soil compaction, Soil density, *Saline water intrusion.

Overirrigation and leakage from soil dams produced a shallow groundwater table of 0.9-1.5 m at the Vaalharts Irrigation Scheme, South Africa. The water table rose further to 0.3-0.6 m from the surface during above average rainfall on occasions during 1974-1976, allowing salt accumulation and reducing yields of wheat, cotton, maize, and groundnuts to nearly zero. There was a correlation between electrical conductivity of the topsoil and wheat yield. Factors having a detrimental influence on seed germination and seedling growth were sodium absorption ratio less than 4, high bulk density, and high soil moisture content. The soil characteristics were a result of mechanical cultivation of the fine sandy soil and the shallow ground water table. Irrigation practices should be improved and drains installed if necessary. (Cassar-FRC)

EFFECT OF SURFACE SEALING ON INFILTRATION,
Kentucky Univ., Lexington. Dept. of Agricultural Engineering.
I. D. Moore.
Transactions of the ASAE, Vol 24, No 6, p 1546-1552, 1561, November/December, 1981. 6 Fig, 8 Tab, 40 Ref.

Descriptors: *Infiltration, *Surface sealing, *Soil water, Surface permeability, Soil types, *Model

studies, Richards equation, Ponding, *Soil properties.

Numerical solutions of Richards' equation showed the effects of surface sealing of soils on infiltration. The three conditions examined in the model were: (1) no seal, (2) developing seal, gradual surface sealing under rainfall activity, and (3) constant seal, a well-established surface seal. Rainfall application rate was 5.3 cm per hour. Measurements on nine A-horizon soils from different counties in Minnesota and Wisconsin were used as model inputs. Results indicated that surface sealing, virtually ignored in infiltration modeling in the past, reduced predicted infiltration rates and volumes by up to 80%. This may account for some of the differences in infiltration behavior observed by different researchers using the same soil type. (Cassar-FRC)

DEEP TILLAGE OF IRRIGATED PULLMAN CLAY LOAM--A LONG-TERM EVALUATION,
Science and Education Administration, Bushland, TX. Conservation and Production Research Lab.
J. T. Musick, D. A. Dusek, and A. D. Schneider.
Transactions of the ASAE, Vol 24, No 6, p 1515-1519, November/December, 1981. 2 Fig, 3 Tab, 20 Ref.

Descriptors: *Irrigation efficiency, *Cultivation, *Infiltration, Drainage, Furrow irrigation, Corn, Wheat, *Crop yield, Sorghum, Grain crops, Soil compaction, Soil density, Agriculture, Water stress, Bushland, Texas, Soil-water-plant relationships.

One-time deep moldboard plowing in 1966 to depths of 0.4, 0.6, and 0.8 meters in slowly permeable Pullman clay loam at Bushland, Texas, increased water intake and crop yield (wheat, sorghum, and corn) during subsequent years. This study reports the results of evaluations in the 1973-79 interval. Soil was disturbed by the deep plowing, which mixed some of the topsoil with lower layers so that the soil had a crumb-type structure, compared with the previous blocky peds. Compared with 0.2 m conventional tillage, the one-time deep tillage increased irrigation water uptake from 120 to 240 mm in 1975 and from 170 to 280 mm in 1978. This effect did not diminish with time. As soil compacted during the growing season from wheel traffic and irrigation water, the water permeability decreased. This was restored by conventional moldboard plowing to 0.2 m. The deep tillage treatment increased sorghum grain yields (in kg per ha) from 6040 to 7290 in 1975 and 9080 to 9960 in 1979. Similarly, corn yields (in kg per ha) were increased from 10,020 to 11,300 in 1977. The increased water intake and the deeper profile wetting of the deeply plowed fields delayed the beginning and reduced the severity of plant water stress. The deep-tillage method is most effective in the normally drier, lower parts of graded furrow irrigated fields, where tailwater runoff can be reduced. It is not recommended for upper sections of the field, where drainage losses may result. (Cassar-FRC)

INFILTRATION INTO TWO-LAYERED SOIL PROFILES,
Kentucky Univ., Lexington. Dept. of Agricultural Engineering.
I. D. Moore, and J. D. Eigel.
Transactions of the ASAE, Vol 24, No 6, p 1496-1503, November/December, 1981. 7 Fig, 5 Tab, 34 Ref.

Descriptors: *Infiltration, *Soil profiles, *Ponding, *Soil water, Model studies, Soil porosity, Green-Ampt Mein-Larson model, Richards equation, Numerical analysis, Loam, Stratification.

Results from the Modified Green-Ampt, Mein-Larson infiltration equations (GAML) for two-layered soil profiles were compared with observed data and results from the numerical solution of Richards' equation. Examples of two-layered soil profiles are plowed soil over undisturbed soil and topsoil over mine spoil. The two-layers of soil used were a Lewiston fine sandy loam (coarse) and a Millville silt loam (fine). Both coarse-over-fine and fine-over-coarse were examined. In the two-layered soil profiles the GAML and numerical models produced similar results (time to surface ponding, infiltration volume, and infiltration rate). Layering sequence was a significant factor in infiltration behavior. Infiltration rates and volumes were lower for fine-over-coarse than for coarse-over-fine stratifications. For the coarse-over-fine profiles there was a general increase in time to ponding as the application rate decreased and surface layer thickness increased. For the fine-over-coarse, layering times to surface ponding predicted by the Modified GAML model were independent of the thickness of the surface layer. However, the time to ponding increased with increasing thickness for the numerical model. Agreement between predicted and observed data ranged from excellent to fair. Best agreement was for the smaller surface layer thicknesses. Both models underpredicted infiltration rates for coarse-over-fine stratifications. (Cassar-FRC)

NOTE ON PUDDLING EFFECTS ON WATER FLOW THROUGH SOILS,
Punjab Agricultural Univ., Ludhiana (India).
B. K. Sinha, S. R. Singh, and R. G. Sharma.
Indian Journal of Agricultural Sciences, Vol 51, No 6, p 460-461, June, 1981. 1 Fig, 3 Ref.

Descriptors: *Irrigation practices, *Puddling, Percolation, Crop yield, *Rice, Irrigation requirements, Water loss, *Soil water.

The effect of puddling intensity on the nature of water flow and irrigation requirements of rice crop were investigated in laboratory and field studies. The response to puddling in different soils varied according to the soil texture. The resistance to water flow, as evidence by specific discharge, was increased in all the soils following puddling. The reduction in specific discharge after the first puddling ranged from 6 to 10 fold at different hydraulic gradients in sand. In sandy loam it was small, especially at lower gradients. In silty clay loam soil the reduction was marginal. Apparently puddling could reduce percolation losses only in coarse-textured soils. The second puddling was less effective than the first in reducing the specific discharge, except in sandy loam soil, where the second puddling might have resulted in a more uniform sealing of pores. Thus structure destruction due to puddling may not be of much importance in reducing water flux through the soil. Puddling altered the nature of water flow, particularly in silty clay loam. Increased puddling intensity in fine textured soils did not effect any significant saving in irrigation water. Evidently fine textured soils need not be puddled if the sole aim is to reduce percolation losses. (Baker-FRC)

WATER MOVEMENT IN UNIFORM SOILS DURING CONSTANT-FLUX INFILTRATION,
Commonwealth Scientific and Industrial Research Organization, Canberra City (Australia). Div. of Environmental Mechanics.
K. M. Perroux, D. E. Smiles, and I. White.
Soil Science Society of America Journal, Vol 45, No 2, p 237-240, March/April, 1981. 5 Fig, 11 Ref.

Descriptors: *Infiltration, *Soil water, Mathematical models, Mathematical equations, Fluctuations, Absorption, Gravity studies, Ponding, *Soil water movement.

Several studies have addressed the problem of predicting water movement and distribution in soils during nonponding rainfall or sprinkler irrigation. While a variety of numerical methods have been successfully applied to flux boundary conditions for a variety of initial conditions, the search for general analytical solutions to the flow equation for the constant-flux boundary condition initially met with less success. This paper presents an analysis for constant-flux infiltration of water in soil based on the flux-concentration relation. The results of laboratory experiments on constant-flux infiltration into columns of fine sand and silty loam are compared with behavior predicted both with and without a gravitational component. The effect of gravity was shown to be small for the early stage. During the early stage it is possible to make sufficiently accurate predictions of moisture profile development using the simpler absorption analysis of White, et al. (1979). (Carroll-FRC)

ESTIMATION OF PRIMARY PRODUCTIVITY IN AQUATIC SYSTEMS USING FREE OXYGEN MEASUREMENTS,
Amsterdam Univ. (Netherlands). Dept. of Aquatic Ecology.
R. Lingeman, and S. Vermij.
Water Resources Bulletin, Vol 16, No 4, p 745-748, August, 1980. 2 Fig, 13 Ref.

Descriptors: *Primary productivity, *Oxygen, *Temperature, Lakes, Productivity, Water temperature, *Model studies, Stratification, Heat transfer, Eddy diffusion, Barlosche Kolk, Netherlands.

One-dimensional models for heat or oxygen transport in aquatic systems have been used by several authors to estimate primary productivity. These methods use free oxygen and temperature measurements at discrete time and depth intervals and assume that the eddy diffusion coefficients of heat and oxygen are interchangeable. This method was applied to data from the Barlosche Kolk, a 3.5 ha lake with maximum depth of 6 m. Steep oxygen gradients and moderate temperature stratification are present in summer, but there is no distinct hypolimnion. Temperature and oxygen were measured hourly at 0.5 m intervals of depth. Primary productivity calculated from these data and the model did not agree with simultaneous measurements of primary productivity by the light and dark bottle method. It was concluded that the one-dimensional model is inadequate for this application because the discrete measurements of temperature and oxygen do not provide sufficient data. A more adequate model should include horizontal transports induced by internal waves along the sheets of steep temperature gradients. Continuous recording of temperature and oxygen may provide necessary data. (Cassar-FRC)

WATER BUDGET COMPUTATIONS FOR A SHALLOW--LAKE OKEECHOBEE, FLORIDA,
Florida Univ., Belle Glade. Agricultural Research and Education Center.
S. F. Shih.
Water Resources Bulletin, Vol 16, No 4, p 724-728, August, 1980. 1 Fig, 1 Tab, 13 Ref.

Descriptors: *Hydrologic budget, *Storage capacity, *Evapotranspiration, Lakes, *Lake Okeechobee, *Florida, Shallow lakes, Marsh plants, Model studies, Evaporation.

The water budget for Lake Okeechobee, Florida, was computed using a model which included marsh plant evapotranspiration. This model was labeled WET and the conventional methods, without the evapotranspiration factor, WOET. Three periods were used to compare the differences in the sum of storage deviation between the two methods. These periods differed in length: testing (1969-74), planning (1963-74), and recorded period (1952-77). The WOET method gave the following sums of stage deviations: 87.42 cm, 231.80 cm, and 284.5 cm for the three periods respectively. These were equivalent to 29, 76, and 93% of the lake volume. The WOET method overestimated storage, as compared with recorded data, for 21 out of 26 years. The WET method reduced the sum of storage deviation by 42, 31, and 49%, respectively, for the three periods. The sums of stage deviations were 50.72 cm, 160. 08 cm, and 144.81 cm, respectively. Storage deviations were overestimated in 15 out of 26 years. (Cassar-FRC)

PHOSPHORUS AVAILABILITY IN LAKE MEMPHREMAGOG AND ITS TRIBUTARIES,

LIBRARY U. OF ILLINOIS CHAMPAIGN

McGill Univ., Montreal (Quebec). Dept. of Biology.
R. H. Peters.
Limnology and Oceanography, Vol 26, No 6, p 1150-1161, 1981. 4 Fig, 3 Tab, 40 Ref.

Descriptors: *Lakes, *Phosphorous, Nutrients, Biomass, *Lake Memphremagog, Canada, Rivers, Limnology, Water analysis.

Water samples were taken from Lake Memphremagog and five of its tributaries. The percentage of total phosphorus in the samples which was biologically available was measured on three dates. The criteria used to measure the percentage of biologically available phosphorus were the distribution of radioactive phosphorus among exchanging fractions and the enzymatic release of soluble phosphorus from particulate phosphorus when stored with chloroform. The available phosphorous in the lake water formed 83% of the total phosphorus. The available phosphorous in rivers was only 18-57% of the total, much less than in the lakes. The most refractory fraction was usually high molecular weight phosphorus, and was separated by gel filtration. Substantial amounts of unavailable phosphorus were also associated with particles and with low molecular weights. Intermediate molecular weight soluble phosphorus was too small a fraction for determining its availability. Variations in the percentage of available phosphorus in natural waters could substantially change the biological effect of a given phosphorus load. (Baker-FRC)

COMPARISONS OF SOLUBLE REACTIVE PHOSPHORUS AND ORTHOPHOSPHORUS CONCENTRATIONS AT AN OFFSHORE STATION IN SOUTHERN LAKE MICHIGAN,
National Oceanic and Atmospheric Administration, Ann Arbor, MI. Great Lakes Environmental Research Lab.
S. J. Tarapchak, and C. Rubitschun.
Journal of Great Lakes Research, Vol 7, No 3, p 290-298, 1981. 2 Fig, 3 Tab, 32 Ref.

Descriptors: *Phosphorus, *Lake Michigan, Lakes, Phosphates, Bioassay, Chemical analysis, *Fate of pollutants, Pollutant identification, Lake sediments, Phytoplankton.

Soluble reactive phosphorus in the epilimnion of southeast Lake Michigan, measured at a station 15 km from shore in May-October 1976, was higher and more variable than previously published measurements. The overall means were 4.9 micrograms P per liter (range 2.0-10.3 micrograms P per liter) using Harvey's method and 3.4 micrograms P per iter (range 1.2-7.7 micrograms P per liter) using the Chamberlain-Shapiro extraction technique. At times there were significant vertical variations in the water column and near the sediment, but the hypolimnion did not accumulate P. Both methods overestimated maximum possible phosphate-P concentrations up to two orders of magnitude. Maximum possible phosphate-P concentrations as measured by Rigler's radiobioassay method were an average of 22.5% of those measured by Harvey's method and 25.6% of those measured by the extraction technique. Several factors which could cause too-high P measurements were investigated. It was concluded that the values were, in fact, higher because high concentrations of particulates were carried out to distances 10-15 km from shore in this region during the extremely wet year 1976. Data suggest that true phosphate concentrations may be lower in the epilimnion of eutrophic lakes than in mesotrophic lakes because of high biological utilization rates and less efficient recycling mechanisms. (Cassar-FRC)

TEMPERATURES AND CURRENTS IN A STRATIFIED LAKE: A TWO-DIMENSIONAL ANALYSIS,
Arizona Univ., Tucson.
J. Henrich, W. Lick, and J. Paul.
Journal of Great Lakes Research, Vol 7, No 3, p 264-275, 1981. 13 Fig, 36 Ref.

Descriptors: *Water temperature, *Water currents, *Stratification, Lakes, Water circulation, Lake circulation, Temperature, Currents, Wind-driven currents, Thermal stratification, *Lake Erie, *Model studies, Thermocline, Turbulent flow, Heat transfer.

A two-dimensional (vertical and horizontal) time-dependent model was used to predict temperatures and currents in a stratified lake comparable to the central basin of Lake Erie. Stratified flow during the time of formation, maintenance, and decay of the thermocline were investigated. Increasing heat flux to the water causes earlier, shallower, and stronger formation of a thermocline. Increasing turbulence causes later, deeper, and weaker thermocline formation. Heat transfer to the sediment in a shallow lake can decrease hypolimnion temperatures by 1 C. Effects of a sinusoidal 24-hour period heat flux and the temperature distribution of thermal radiation are limited to the near surface region and do not change thermocline formation. Wind stress perpendicular to the cross-section results in a stronger, narrower return flow just above the thermocline than does wind parallel to the cross-section. Wind reversal shifts the orientation of the thermocline so that the hypolimnion waters are shifted in the upwind direction and the thermocline becomes deeper in the downwind direction. If wind has not reversed by 50 days, a second thermocline can form above the first thermocline. In general, calculated results agreed with observations. (Cassar-FRC)
W82-04378

WINTER TEMPERATURE STRUCTURE IN LAKE HURON,
National Oceanic and Atmospheric Administration, Ann Arbor, MI. Great Lakes Environmental Research Lab.
G. S. Miller, and J. H. Saylor.
Journal of Great Lakes Research, Vol 7, No 3, p 201-206, 1981. 8 Fig, 1 Tab, 13 Ref.

Descriptors: *Water temperature, Stratification, *Mixing, Lakes, *Lake Huron, Temperature, Water depth, *Thermal stratification, Water circulation, Seasonal variation.

Water temperatures were continuously recorded at 17 sites in Lake Huron during the winter of 1974-75 at depths of 15,25, and 50 m below the surface and 2 m from the bottom. In the beginning of fall overturn in November several warm pulses were observed at depths below 100 m. The shallower southern basin was already isothermal at 7 C. Monthly isotherms followed the bathymetry of the lake. The shore regions rapidly cooled to near freezing by early February. The deep northern basin did not reach a minimum of 1.5 C until mid-April. Differences between mean monthly temperatures at the 15 and 25 m depths were < 0.3 C during December-April. In the deep basins a weak winter thermocline, temperature difference 1.5 C, developed in March and nearly disappeared by April. (Cassar-FRC)
W82-04381

FACTORS REGULATING THE SPATIAL DISTRIBUTION OF THE FILAMENTOUS ALGA PITHOPHORA OEDOGONIA (CHLOROPHYCEAE) IN AN INDIANA LAKE,
Purdue Univ., Lafayette, IN. Dept. of Botany and Plant Pathology.
D. F. Spencer, and C. A. Lembi.
Journal of Phycology, Vol 17, No 2, p 168-173, 1981. 8 Fig, 4 Tab, 26 Ref.

Descriptors: *Algal growth, *Lakes, Littoral environment, Littoral zone, Algae, Eutrophication, Nitrogen, Phosphorus, *Nutrients, Limiting factors, Limiting nutrients.

A combined field and laboratory study was designed to determine the factors regulating the spatial distribution of Pithophora oedogonia in Surrey Lake, Indiana. Surrey Lake is small and shallow, man-made, with a water flow from south to north. The inflowing stream drains a watershed of about 1128 ha, 62% of which is agricultural land and pastures, 21% woodland, and 16% residential properties. Water samples and algal biomass samples were collected from May 1978 to December 1979. The biomass was greater in the littoral than in the pelagial region. Although mean soluble reactive phosphorus concentrations did not differ significantly in the open vs cove water, nitrate concentrations were almost six times higher in the latter. Nitrogen limiting conditions were prevalent in the open water section of the lake. Alkaline phosphatase and dark ammonia uptake analyses on field collected filaments from the shallow and deep water sections confirmed the hypothesis that nitrate is the major factor limiting growth of Pithophora in Surrey Lake. (Baker-FRC)

ULTRAPLANKTON BIOMASS, PRODUCTIVITY AND EFFICIENCY IN LAC MATAMEC, A PRECAMBRIAN SHIELD LAKE,
Waterloo Univ., (Ontario). Dept. of Biology.
P. E. Ross, and H. C. Duthie.
Journal of Phycology, Vol 17, No 2, p 181-186, 1981. 5 Fig, 3 Tab, 44 Ref.

Descriptors: *Lakes, *Plankton, Aquatic life, Phytoplankton, Biomass, Photosynthesis, *Canada, Eutrophication, *Lake Matamec, Aquatic productivity, Oligotrophic lakes, *Quebec.

Extremely low phosphorus concentrations were found in Lac Matamec, suggesting that it must be extremely oligotrophic. The summer range of chlorophyll concentrations places the lake among the least productive in the world. Since blue light is attenuated most quickly with depth and red light the least, a characteristic typical of water rich in dissolved humic substances, the lake may also be dystrophic. Further evidence for a dystrophic condition lies in the relationship between chlorophyll a and light extinction. In Lac Matamec there is virtually no correlation between the two parameters of chlorophyll and transparency. The ultraplankton accounted for an average of 47% of the biomass of the lake, but yet was responsible for 71% of the carbon fixation. The ultraplankton had the highest photosynthetic efficiencies of the three classes, ultraplankton, nanoplankton, and plankton. The importance of the ultraplankton in the ecology of Lac Matamec is enhanced by the marked scarcity of littoral habitat. High surface:volume ratios may explain the high efficiency of the ultraplankton. (Baker-FRC)

Descriptors: Ecosystems, *Ultraviolet radiation, Ozone, Microorganisms, Thermocline, *Solar radiation, *Plankton, Plankton-sunlight-water movement relationships, Radiation regime, UV-B.

Previous studies have shown the planktonic organisms of various natural water bodies to be quite sensitive to the levels of solar ultraviolet radiation incident at the water surface in summer. It has been assumed that the majority of the phytoplankton are simply carried about in the mass of the water which they inhabit with little controlof their position or sunlight exposure. Photosynthetic microorganisms must strike a delicate balance with regard to solar radiation; they must obtain enough visible light for adequate photosynthesis while avoiding an excessive exposure to the injurious solar UV-B radiation. It is proposed that the circulation in natural waters is such that organisms can 'ride' the current to obtain radiation exposures approximating the average radiation level of the euphotic zone. If exposure tends to become excessive, the plankton 'drop out' of the circulation into the relatively immobile thermocline region until conditionss are favorable for a return to the highly illuminated surface waters. Observations with two

species of aquatic plants generally cofirm the proposed model. A radiation regime where the entire population receives essentially the same exposure to sunlight could be substantially more efficient in using the available light for photosynthesis than the 'static' model where it is assumed that part of the population is overly exposed and another segment continuosly dwells deep in the water in very dim light.

RIDGE REGRESSION TECHNIQUES APPLIED TO LANDSAT INVESTIGATION OF WATER QUALITY IN LAKE OKEECHOBEE,
Florida Univ., Belle Glade. Dept. of Agricultural Engineering.
S. F. Shih, and J. C. Gervin.
Water Resources Bulletin, Vol 16, No 5, p 790-796, October, 1980. 1 Fig, 4 Tab, 10 Ref.

Descriptors: *Eutrophic lakes, *Water quality, Light penetration, Regression analysis, Lakes, Mathematical studies, *Turbidity, Water analysis, Opacity, Eutrophication, *Chlorophyll a, *Suspended sediments, Remote sensing, *Landsat, *Lake Okeechobee, Florida.

Studies were made on the eutrophic Lake Okeechobee in Florida to derive a relationship between the chlorophyll a, turbidity and suspended sediment water quality parameters and Landsat radiance values applicable over several days and to compare the regression results for two different levels of accuracy in measuring Landsat radiance values. The general concepts of ridge regression techniques were applied to satellite data analysis. Landsat radiance values processed at a double level of precision gave a better solution when applied to the estimation of water quality parameters. Ridge regression analysis for double level accuracy eliminated problems of multicollinearity and reduced the total mean square error by 13 to 20% and the confidence interval by 6 to 28% when compared to ordinary least square analysis. The stabilized regression equations and individual parameter estimates are more readily interpretable from the standpoint of lake water quality analysis. (Geiger-FRC)

EFFECT OF TEMPERATURE ON HETEROTROPHIC GLUCOSE UPTAKE, MINERALIZATION, AND TURNOVER RATES IN LAKE SEDIMENTS,
Orange Free State Univ., Bloemfontein (South Africa). Inst. for Environmental Sciences.
D. F. Toerien, and B. Cavari.
Applied and Environmental Microbiology, Vol 43, No 1, p 1-5, 1982. 6 Tab, 18 Ref.

Descriptors: *Glucose, *Bottom sediments, *Lakes, Sedimentation, Chemical analysis, Absorption, Metabolism, Mineralization, *Lake Kinneret, *Israel, *Temperature effects, Microbial degradation.

Using sediments from Lake Kinneret, Israel, an evaluation was made of the effect of temperature on the maximum uptake rate, in situ substrate concentration and turnover rate for glucose uptake and mineralization. The major features of Lake Kinneret sediments are a high percentage of fine grain material, an abundance of calcium carbonate, and a dominance of montmorillonite in the clay fraction. The maximum uptake rate was similar when aerobic and anaerobic conditions were used in the assay procedure. The maximum uptake rate values for carbon dioxide evolution (glucose mineralization) ranged from 2.75 to 4.77 micrograms of CO2/g/hr. No consistent pattern was observed in glucose mineralization for the aerobic or anaerobic sediments when assayed aerobically or anaerobically. All temperature experiments were run under aerobic conditions. It was concluded that the maximum uptake rate and the turnover rates of glucose uptake and mineralization were temperature dependent. The glucose respiration/uptake ratio was not greatly influenced by the presence or absence of oxygen or by different assay temperatures. (Baker-FRC)

CONTRIBUTION OF PARTICLE-BOUND BACTERIA TO TOTAL MICROHETEROTROPHIC ACTIVITY IN FIVE PONDS AND TWO MARSHES,
Harvard Univ., Cambridge, MA. Div. of Applied Sciences.
D. Kirchman, and R. Mitchell.
Applied and Environmental Microbiology, Vol 43, No 1, p 200-209, 1982. 2 Fig, 5 Tab, 46 Ref.

Descriptors: *Ponds, *Bacteria, *Marshes, Ecosystems, Biomass, Particulate matter, Microbiological studies, Coastal mareshes, Salinity, Filtration, Metabolism, Organic compounds, *Coastal waters.

This report compares the number and heterotrophic activity of epibacteria and unattached bacteria in five coastal ponds and two marshes. It is suggested that, although the numbers of epibacteria are low, they may contribute significantly to the turnover of dissolved organic matter in selected aquatic ecosystems. The data presented support the hypothesis that bacteria associated with particulate matter are metabolically more active per cell than unattached bacteria. The particle-bound bacteria incorporated a large proportion of glucose and glutamate in selected aquatic systems. The uptake per cell was significantly higher for epibacteria than for unattached bacteria in all systems. Particle-bound bacteria were more important than total bacteria in those waters with a high particle concentration and not flushed regularly by tides in contrast to waters with a low particle concentration and being flushed regularly. The study indicates that the importance of epibacteria may be greatly underestimated due to their small numbers. (Baker-FRC)

HORIZONTAL DISTRIBUTION AND FLUX OF PHOSPHORUS IN FISH LAKE, WISCONSIN,
Wisconsin Univ.-Madison.
R. J. Erickson.
PhD Thesis, August, 1980. 189 p, 13 Fig, 19 Tab, 110 Ref, 2 Append. University Microfilms International, Ann Arbor, MI; Order No GAX80-28177.

Descriptors: *Lakes, *Littoral environment, *Phosphorus, Sediments, Mass transfer, *Fish Lake, *Distribution patterns, *Wisconsin, Pelagial sources.

Effects of the littoral zone on epilimnetic phosphorus were investigated in Fish Lake, Wisconsin, a mesoeutrophic, calcareous, seepage lake with an area of 88 ha, maximum depth of 19 m, and mean depth of 6.3 m. The littoral comprises 55% of the lake's area and is diverse with respect to sediment texture, angiosperm development, and hydraulic turnover time with the pelagial. Phosphorus concentrations were positively correlated with areas with (a) fine sediment and significant angiosperm development, (b) limited exchange of water with the pelagial, and (c) substantial runoff contributions to sediments. During turnover, pelagial phosphorus concentrations equalled or exceeded littoral concentrations because the hypolimnetic phosphorus pool became a significant phosphorus source to surface waters. Littoral phorphorus concentrations were not correlated with groundwater seepage and showed only a minor response to surface runoff events. This suggests that internal loading from littoral sediments was the major cause of these gradients rather than temporary storage of external loadings. The existence of internal loading was confirmed by observations of phosphorus accretion in littoral enclosures. Littoral-to-pelagial transport was the major phosphorus source to the pelagial during summer stratification, corresponding to 300-1500% of the pelagial phosphorus pool. Net transport of phosphorus from the littoral requires a source of phosphorus to replenish littoral sediments. Measurements in this investigation suggested that external loading was a major immediate source of this phosphorus, but that return of phosphorus from midlake to the littoral during turnover could also be important. SIMULATION AND VERIFICATION OF LAKE ONTARIO'S MEAN STATE,
National Oceanic and Atmospheric Administration, Ann Arbor, MI. Great Lakes Environmental Research Lab.
J. C. K. Huang, and P. W. Sloss.
Journal of Physical Oceanography, Vol 11, No 11, p 1548-1566, November, 1981. 11 Fig, 2 Tab, 35 Ref.

Descriptors: *Model studies, *Lakes, Thermal stratification, Stratification, *Lake Ontario, Great Lakes, Flow pattern, Wind, Mathematical studies, *Limnology.

A numerical dynamic model was developed for Lake Ontario based on primitive equations. All major current generating mechanisms were taken into account. The model is used for hindcasting the mean state in Lake Ontario during the International Field Year for the Great Lakes (IFYGL). Two simulations were carried out in July and December as representations of summer and winter. One simulation was done under the respective monthly mean steady frocing and the other under the respective hourly, time dependent atmospheric forcing. The constant forcing simulation resulted in a typical two gyre circulation pattern when the wind blew approximately parallel to the major axis of the lake. In the time dependent variable forcing simulation, the high frequency atmosheric fluctuations have not only excited strong inertial motions, but also generated mesoscale eddied near the downwind end boundary. Large scale low frequency topographic waves, propagating cyclonically at a phase speed of 60 cm/second, are also shown in the simulations. the generation, evolution, and dissipation of topographic waves, as well as mesoscale eddies can be expalined satisfactorily by the principle of conservation of potential vorticity. In the July case the lake dynamics are more complicated owing to the presence of thermal stratifications in addition to the mechanical forcing. (Baker-FRC)

STRUCTURE OF THE FLOW WITHIN THE COASTAL BOUNDARY LAYER OF THE GREAT LAKES,
Canada Centre for Inland Waters, Burlington (Ontario).
C. R. Murthy, and D. S. Dunbar.
Journal of Physical Oceanography, Vol 11, No 11, p 1567-1577, November, 1981. 14 Fig, 1 Tab, 8 Ref.

Descriptors: *Boundary layers, *Lakes, Lake Huron, Boundaries, *Great Lakes, Lake coasts, Flow patterns, Flow, Coastal waters, Nearshore processes, Water currents.

Detailed observations on properties of the nearshore flow were noted at Douglas Point, Lake Huron. A network of current meters deployed in a coastal chain perpendicular to the local shoreline was used to obtain time series flow data. Data from these points was analyzed to resolve the mean flow

LIBRARY U. OF ILL. - URBANA-CHAMPAIGN

properties, horizontal turbulence characteristics and the kinetic energy within the coastal boundary layer. The variability of these parameters as a function of the distance from shore for an episode during which persistent short-parallel currents prevailed for several days has revealed two distinct boundary layers, an inner boundary layer dominated by bottom and shore friction and an outer boundary layer as a consequence of the adjustments of inertial oscillations to the lateral boundary. If the width of the frictional boundary layer is taken as the distance to the point where the kinetic energy of currents peak, it is about 2 km at Douglas Point. As the width of the inertial boundary layer, the distance to the point where inertial oscillations begin to dominate short parallel flow may be taken. This width at Douglas Point is about 8 to 10 km. WIND MIXING AND RESTRATIFICATION IN A LAKE NEAR THE TEMPERATURE OF MAXIMUM DENSITY,
Department of the Environment, Victoria (British Columbia). Inst. of Ocean Sciences.
D. M. Farmer, and E. Carmack.
Journal of Physical Oceanography, Vol 11, No 11, p 1516-1533, November, 1981. 13 fig, 2 Tab, 34 Ref.

Descriptors: *Thermal stratification, *Wind, Mixing, Density, *Destratification, *Lakes, Temperature effects, Seasonal variation, Convection, Babine Lake, *British Columbia, Canada.

Wind mixing and restratification were studied under conditions of a density maximum during the cooling of a freshwater lake. A mixed layer model was used to explore the concepts. The model incorporated both nonlinearity and pressure dependence in the equation of state. The results offer a basis for interpreting temperature structure in Babine Lake and for making some more general observations on mixing and restratification. After summer stratification is destroyed by wind mixing and convection in autumn, the lake is essentially isothermal as it cools through 4 degrees C. The coefficient of expansion becomes so small near this temperature that pressure effects which play little part in the dynamics at higher temperatures can dominate the stability. The transition between forced and free convection is marked at the depth where the local temperature equals the temperature of maximum density at constant pressure. Above this transition depth the wind must work against buoyance forces during cooling. Below this temperature the water is gravitionally unstable. Conditional instabilities occur which allow for a downward movement of initially stable water, leading to gravitational instability. As the lake cools the stability becomes less sensitive to pressure, and a given heat flux produces a progressively greater buoyancy flux, leading to the process of restratification. (Baker-FRC)

DETERMINATION OF CHARACTERISTIC VALUES FOR PHYSICAL AND CHEMICAL LAKE SEDIMENT PARAMETERS,
National Swedish Environment Protection Board, Uppsala (Sweden).
L. Hakanson.
Water Resources Research, Vol 17, No 6, p 1625-1640, December, 1981. 20 Fig, 13 Tab, 31 Ref.

Descriptors: *Sediments, *Lake sediments, *Physical properties, *Path of pollutants, Lakes, Mercury, Organic matter, Nitrogen, Phosphorus, Zinc, Heavy metals, Metals, Nutrients, Model studies, Characteristic values, Statistical analysis, *Sweden.

Characteristic values are determined for physical and chemical sediment parameters in lakes. The various physical sediment parameters (water content, bulk density, organic content, grain siize, degree of compaction, and sediment depth) are related to each other and to the sediment water conoent, a key parameter. The areal distribution of these physical parameters is described by a general formula, which is used with data for 5 Swedish lakes (Hjalmaren, Vanern, northern Vattern, western Malaren, and Ekoln). This relationship provides a way to determine the physically relevant characteristic values, not just traditional statistical values. Results show that (1) the distribution of the physical sediment parameters depends on the water depth, (2) the standard deviation around the mean is large in shallow waters where erosion, transportation, and fine sediments occur, (3) the spread decreases with increasing water depth, and (4) the spread is relatively small at water depths within the zone of accumulation. A formula is given for estimating the critical water content separating areas of accumulation from zones of transportation. Characteristic values may also be determined for chemical parameters showing high correlation with water content (the noncontaminating parameters). This procedure cannot be used on pollutants, which are usually distributed as distinct tongues with concentrations decreasing with increasing distance from the pollution source. Characteristic values for contaminating substances such as mercury may be determined from a map showing the areal distribution pattern as the areal median value. (Cassar-FRC)

BIOGENIC CALCITE STRUCTURES FORMING IN LAKE FRYXELL, ANTARCTICA,
Virginia Polytechnic Inst. and State Univ., Blacksburg. Dept. of Biology.
R. A. Wharton, Jr., B. C. Parker, G. M. Simmons, Jr., K. G. Seaburg, and F. G. Love.
Nature (London), Vol 295, No 5848, p 403-405, February 4, 1982. 2 Fig, 1 Tab, 18 Ref.

Descriptors: *Polar regions, *Lakes, Calcite, *Lake Fryxell, *Antarctic, Precambrian era, Microorganisms, Sedimentation, Algal growth, Inflow, Meltwater.

Observations in Lake Fryxell, Antarctica, revealed biogenic calcite structures not observed in other studies of Antarctic lakes. These structures were laminated, indurate, unbranched, and had either a vertical or a horizontal orientation. It was inferred that these calcite structures are biogenic in origin, due to the presence of an actively metabolizing algal mat on their surface and an internal composition of filamentous blue-green algal cell wall fragments, diatom frustules and calcite crystals. Lake Fryxell is located at the eastern end of Taylor Valley in southern Victoria Land. The lake lacks outgoing streams, and receives sediment, salts and nutrients from glacial meltstreams during the austral summer. The vertical calcite structures in the lake apparently resulted from the growth of the algal mat in dimly-lit shallow, non-turbulent water. Further study may offer insight into the palaeoecology of Precambrian stromatolites. (Baker-FRC)

PREDICTION OF THE CIRCULATION IN RESERVOIRS,
Liverpool Univ. (England). Dept. of Civil Engineering.
K. H. M. Ali, and D. Pateman.
Proceedings of the Institution of Civil Engineers, Part 2: Research and Theory, Vol 71, No 2, p 427-461, June, 1981. 27 Fig, 20 Ref.

Descriptors: *Reservoirs, *Water circulation, *Wind-driven currents, Lake circulation, *Model studies, Water currents, Coriolis force, Shallow lakes.

Circulation in shallow, open reservoirs was analyzed analytically and experimentally. The theoretical work considered inflows and outflows and geostrophic and wind effects. Experimental work was done on three circular reservoirs with radii of 0.73 to 3.68 m, using dye and illuminated surface floats. In a circular reservoir tangential or radial jets caused circulation patterns dependent on the Reynolds number of the jet and the aspect ratio of the reservoir. Outlet dimensions had little influence on circulation patterns. Circulation was predicted for prototype reservoirs using the equations developed in this paper. Water circulation caused by wind and the earth's rotation were highly dependent on reservoir water depth, wind shear stress at the water surface, and eddy viscosity. Predicted circulation was not applicable to the peripheral areas of the reservoirs. Diagrams for circulation in the experimental reservoirs are given for different combinations of wind stress, eddy viscosity, Coriolis factor, jet velocity, and water depth. (Circulation patterns for two irregularly-shaped reservoirs at Liverpool are also given. (Cassar-FRC)

LIMNOLOGICAL CHARACTERISTICS OF EUTROPHIC LAKE ISTOKPOGA, FLORIDA,
Bucknell Univ., Lewisburg, PA. Dept. of Biology.
W. F. McDiffett.
Florida Scientist, Vol 44, No 3, p 172-181, 1981. 4 Fig, 1 Tab, 11 Ref.

Descriptors: *Eutrophication, *Limnology, Lakes, Nutrients, Phosphorus, Algal growth, *Lake Istokpoga, *Florida, Field studies, Path of pollutants, Primary productivity, Agricultural runoff, Watersheds.

The results of a comprehensive limnological investigation of Lake Istokpoga are described. This lake represents a significant component of the Lake Okeechobee drainage basin. Nutrient enrichment bioassay experiments are also discussed. The study area is located in Highlands County, south-central Florida, just east of the Lake Wales sand ridge. The surface area is about 112 square kilometers, with a drainage basin of about 1700 square kilometers. The physico-chemical data indicate a well mixed body of water. The large surface area in conjunction with a shallow depth facilitates wind-generated mixing. The influent streams are significant contributors of nutrients to the lake; high primary productivity levels are the result. Irrigation projects contribute significant amounts of nutrients in runoff during dry periods. Nutrient enrichment experiments indicated that primary productivity in the lake was chiefly limited by phosphorus. Seasonal differences in response to ambient algal populations may have been responsible. Taken as a whole, the data suggest that Lake Istokpoga is a eutrophic system. (Baker-FRC)

THE BIOGEOCHEMISTRY OF SULFUR IN TWO SMALL LAKES,
R. B. Cook.
PhD Thesis, 1981. 267 p, 46 Fig, 45 Tab, 97 Ref, 3 Append. University Microfilms International, Ann Arbor, MI; Order No GAX81-13497.

Descriptors: *Biochemistry, *Lakes, *Sulfur, Bacteria, Sediments, Alkalinity, Chemical reactions, Chemical reduction, Chemical model.

The sulfur cycle in natural systems is greatly influenced by the presence of anoxic zones in which sulfate may be bacterially reduced to form labile H2S. The two lakes examined in this study, Lake 227 and Lake 223 at the Experimental Lakes Area, northwestern Ontario, have seasonally anoxic hypolimnia that exhibit bacterial sulfate reduction. Sulfate reduction rates were estimated from the decrease in hypolimnion sulfate concentrations during thermal and winter stagnation for both lakes and from a water column numerical model in L227. The anoxic breakdown of organic matter, as indicated by NH3 production, liberates S from amino acids and proteins at a rate 1/3 that of sulfate reduction in L227 and 4% of sulfate reduction in L223. Comparison of predicted amounts of FeS precipitated with actually measured FeS shows that there is approximately 3 years accumulation in L223 and greater than 10 years in L227. In L223, all of the FeS that formed during the acidification experiment is present in the sediment. The residence times for sulfate in both lakes are similar to the water residence times (2-6 years). A chemical model has been derived which predicts the increase in alkalinity from ammonia production, sulfate reduction, Fe 2+ production and FeS precipitation and compares this to the observed increase in alkalinity. This model shows that alkalinity gained by Fe 2+ production and FeS precipitation and compares this to the observed increase in alkalinity. This model shows that alkalinity gained by Fe 2+ is lost from the lake system during the invasion of oxygen at fall overturn

when Fe 2+ precipitates as an iron(III) hydroxide. (Sinha-OEIS)

ADDITION OF RADIOCARBON TO THE MIXED-LAYERS OF TWO SMALL LAKES: PRIMARY PRODUCTION, GAS EXCHANGE, SEDIMENTATION AND CARBON BUDGET,
P. M. Bower.
PhD Thesis, 1981. 263 p, 49 Fig, 53 Tab, 104 Ref, 2 Append. University Microfilms International, Ann Arbor, MI; Order No GAX81-25254.

Descriptors: *Lakes, *Primary productivity, *Phytoplankton, *Sedimentation, *Carbon cycle, Photosynthesis, Carbon radioisotopes, Mixed layers, Dimictic lakes, Gas exchange.

Addition of radiocarbon to the mixed-layers of two small dimictic lakes had made it possible to assess the validity of enclosing natural phytoplankton populations in bottles for the purpose of estimating primary production. Productivity results for the incubator-model averaged from 0.77 to 0.93 of the whole-lake values depending upon the choice of variables as input to the model. During a period of very high productivity, the 16 hour in situ incubations underestimated the whole-lake results by an average 60%, but the performance of the incubator-model was not affected during this time. Strong surface inhibition of photosynthesis was observed in the vertical profiles of production for the 4 and 16 hour in situ incubations but it was never quantitatively significant for the incubator-model. It is argued that this strong surface depression of photosynthesis is an artifact of the stationary position of the bottles and the unnaturally long exposure to supraoptimal light. A correction for daytime respiration of C14 incorporated on previous days suggests that whole-lake productivity is significantly enhanced over that measured in bottles. The fate of C14 was also monitored in the dissolved inorganic, dissolved and particulate organic, and sediment organic fractions. (Sinha-OEIS)

SUNFLOWER YIELD VS. WATER DEFICITS IN MAJOR GROWTH PERIODS,
North Dakota State Univ., Fargo. Dept. of Agricultural Engineering.
E. C. Stegman, and G. W. Lemert.
Transactions of the ASAE, Vol 24, No 6, p 1533-1538, 1545, November/December, 1981. 9 Fig, 2 Tab, 14 Ref.

Descriptors: *Water stress, *Evapotranspiration, *Irrigation requirements, *Sunflower, Seeds, Crop yield, Water requirements, Water use, *Growth stages, North Dakota, Root zone, Plant growth, Soil water.

Water stress was applied to several growth stages of sunflower (hybrid 894): planting to bud, bud to last anther, and last anther to physiologic maturity. Stress level, based on degree of soil water depletion and an allowable level of leaf xylem pressure depression in mid-afternoon, was generally limited to one of the three growth stages. Seed yields vs. seasonal evapotranspiration showed a linear relationship for the upper bound function near 84.3 kg per ha per cm. Maximum yields at two North Dakota sites were 2900 kg per ha (seasonal evapotranspiration, 47 cm) and 3400 kg per ha (seasonal evapotranspiration, 51 cm). On a relative scale the upper bound slope indicated a potential yield loss of 1.3% per 1.0% decline in seasonal evapotranspiration. In this climate near potential yield was attained when available root zone storage capacity was not less than 50-60% in the planting to bud period, 30-40% in the bud to last anther period, and 50-60% in the seed filling period. Reductions of 20% in water requirements are possible with appropriate irrigation regimes. (Cassar-FRC)

EFFECTS OF DECREASED WATERING ON CROP YIELDS,
New Mexico State Univ., Las Cruces. Dept. of Agricultural Engineering.
T. Sammis, and J. Guitar.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-211442, Price codes: A03 in paper copy, A01 in microfiche. WRRI Report No 36, August, 1981. 29 p, 3 Fig, 9 Tab, 23 Ref. OWRT-A-063-NMEX(1).

Descriptors: *Alfalfa, *Cotton, *Crop response, Sprinkler irrigation, Lysimeters, Consumptive use, Irrigation deficit, *New Mexico, *Soil-water-plant relationships, Water production function.

Cotton and alfalfa were irrigated for three years at Las Cruces, with a range of water levels using a sprinkler-line source to determine yield and evapotranspiration under deficit irrigation. Alfalfa was grown at five locations and cotton was grown at two locations in New Mexico using flood irrigated nonweighing lysimeters to measure the yield and evapotranspiration under nonlimiting soil-moisture conditions. A linear water-production function was observed for alfalfa. This function appeared to be transferable to any location in New Mexico, based on the data from five locations within the state. The New Mexico relationship was statistically the same as alfalfa water-production functions for Nebraska and North Dakota. A linear water-production function was also observed for cotton, but was applicable only for the two areas in southern New Mexico where the study was conducted. This study indicated that biomass production may require the same amount of evapotranspiration regardless of site and management differences, as in the case of alfalfa, but that lint or seed production per unit of water will vary from place to place and from year to year.

EFFECTS OF SOIL MOISTURE, PLANTING DATE, AND WEEDS ON CEREAL YIELDS (EFFETS DE L'HUMIDITE DU SOL, DES DATES DE SEMIS ET DES MAUVAISES HERBES SUR LE RENDEMENT DES CEREALES),
Department of Agriculture, Sainte-Foy (Quebec).
J. M. Deschenes, and J. P. Dubuc.
Canadian Journal of Plant Science, Vol 61, No 4, p 851-857, December, 1981. 4 Tab, 17 Ref. English summary.

Descriptors: *Irrigation effects, *Soil-water-plant relationships, *Planting management, *Crop yield, Grain crops, *Cereal crops, Wheat, Oats, Barley, Weeds, Plant growth, Soil temperature, *Quebec.

An observed increase in grain yield from early sowing was investigated using two seeding dates (early and late May), two soil moisture levels (natural precipitation and natural plus irrigation with 25 mm of water per week), and three crops (oats, barley, and wheat). Studies were conducted in the field and under greenhouse conditions in Quebec's St. Andre sandy loam during 1976, 1977, and 1979. In the field early seeding plus irrigation increased yields, but the difference in planting time was more significant than the difference in soil moisture levels. Irrigated, late-planted cereals produced 80% of the yield of unirrigated, early-planted cereals. More than 50% of the yield variation was explained by the soil thermal units between sowing and emergence and the total amount of water between emergence and heading. Greenhouse results were similar to field results except that the effect of soil moisture was more evident. Weeds did not play an important role. Best cereal yields in this climate and soil are obtained by cool soil temperatures at seeding and high soil moisture between emergence and heading. Early May sowing fulfills these conditions. SORGHUM AND BARLEY IN SOUTHERN ALBERTA: GRAIN YIELD RESPONSE TO IRRIGATION AND FERTILIZER,
Department of Agriculture, Lethbridge (Alberta).
E. H. Hobbs, and K. K. Krogman.
Canadian Journal of Plant Science, Vol 61, No 4, p 837-842, 1981. 3 Fig, 3 Tab, 9 Ref.

Descriptors: *Water use efficiency, *Soil-water-plant relationships, *Irrigation requirements, Grain crops, *Sorghum, *Barley, *Alberta, Crop yield, Fertilizers, Plant growth.

Grain sorghum and barley were compared with the respect to seasonal water requirements, interaction between water use and applied N fertilizer, and water use efficiency. Sorghum's seasonal water use was 500 mm, 20% greater than for barley because sorghum's growing season is 2 months longer. Peak daily water uses were 6 mm for sorghum and 5 mm for barley. With adequate irrigation both crops showed a linear yield response to applied N up to 80 kg per ha. However, under dryland conditions fertilizer had little effect on sorghum yield. Water use efficiency decreased with increasing water availability for both crops. Maximum yields were achieved under irrigation. In 1979, a growing season favorable for sorghum (warm fall), water use efficiency was close to 1.25 kg grain per cu m of water for complete season irrigation and early season irrigation regimes for both sorghum and barley. Sorghum grain yield was 6900 kg per ha. In 1978, an unfavorable year for sorghum, water use efficiency (in kg grain per cu m of water) was between 0.5 and 1.0 with or without irrigation; 1.25 for irrigated barley and 2.1 for nonirrigated barley. COMPARISON OF PRESSURE CHAMBER AND PSYCHROMETER ESTIMATES OF LEAF WATER POTENTIAL IN RICE,
International Rice Research Inst., Los Banos, Laguna (Philippines).
J. C. O'Toole, and T. B. Moya.
Plant and Soil, Vol 62, No 2, p 313-317, 1981. 1 Fig, 2 Tab, 7 Ref.

Descriptors: *Water potentials, *Leaves, Experimental design, *Rice, Dewpoint, Hydrometers, Hydrometry, Water analysis, Plant water potential, Measuring instruments.

Two rice cultivars, IR 2035-117-3, a modern semidwarf breeding line from the International Rice Research Institute, and Dular, a tall traditional cultivar from northeast India, were grown in 25 cm deep containers in a well fertilized clay-loam soil. Rice leaves were sampled for water potential between 8 and 9 A.M. on each sample date. Measurements of leaf water potential were made on the two cultivars by two measurement methods, from stress and control treatments and from protected and unprotected leaf handling prior to pressure chamber measurement. Sampling was accomplished over a 26 day period. Protection of leaf samples against water loss during excision, transport and handling was found to be more important at higher leaf water potentials. The two cultivars used appeared to differ in their response to protection of the leaf sample. These results serve to further caution pressure chamber users on extrapolating comparisons between the two measurement methods and between tissue handling techniques even with a single crop species. Root and shoot growth data are presented for Phaseolous plants grown under two conditions of

LIBRARY U. of I. - URBANA CHAMPAIGN

light intensity, and discussion is offered on how the distribution of various sizes of roots and their maturation might be related to the mean water transport coefficients and the growth rates for the whole root system. Plants were grown in aerated nutrient solution for 41 days in a greenhouse, under two light intensities, 425 and 300 microE/square meter/second. Determinations were made of leaf area, root area ratios, distribution of root sizes, and the fraction of the total root surface area of each root class. For plants with leaf and root areas greater than 1000 square centimeters, all of these parameters remained stable. They were not changed by light intensity or by growth rate. The mean root system hydraulic conductance appeared to be related to plant size rather than to plant age. In small plants the conductance was very low. Conductance increased about sixfold and peaked when the root systems reached about 1000 square centimeters in surface area. When the root size distribution stabilized in plants larger than 1000 square centimeters conductance gradually declined, probably because of suberization or some other growth related factor. The same pattern of relationships between root system size, root size distribution and hydraulic conductance was noted in plants grown at lower light intensity, except that the overall hydraulic conductance was consistently lower for plants of similar sizes. 2J. Erosion and Sedimentation

TRANSVERSE BED SLOPE IN ALLUVIAL CHANNEL BENDS,
Iowa Univ., Iowa City. Inst. of Hydrological Research.
A. J. Odgaard.
Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 107, No HY12, p 1677-1694, December, 1981. 7 Fig, 2 Tab, 22 Ref.

Descriptors: *Sediment transport, *Slope degradation, *River beds, *Model studies, *Channel erosion, Channel morphology, Channel flow, Banks, Stream erosion, Streambeds, Sacramento River, Shear stress, Particle size, Alluvial channels, Bed load.

Existing models for the prediction of the steady-state transverse bed slope in channel bends and an alternative model developed in this paper were compared using laboratory and field data from the Sacramento River. Flows in alluvial channel bends are difficult to describe because of the helical flow pattern in the bend and its interactionwith the topography of the channel bed. Strong secondary currents combined with a transverse slope of the bed, deeper toward the outer bank, undermine and erode the outer bank. Existing models are based on equations of motion for the sediment particles in the bed load, whereas the writer's model is based on the assumption that the bed topography is determined by the critical conditions for sediment entrainment. All models gave reasonable agreement between measured and predicted slopes at smaller transverse slopes. At larger slopes the writer's model and one other were the only ones giving acceptable agreement. Grain size is a key parameter in all models, but there is no technique which can simulate the spatial variation of the grain size. (Cassar-FRC)

SEDIMENTATION RATES AND DEPOSITIONAL PROCESSES IN LAKE SUPERIOR FROM PB210 GEOCHRONOLOGY,
Minnesota Univ., Minneapolis. Dept. of Geology and Geophysics.
J. E. Evans, T. C. Johnson, E. C. Alexander, Jr., R. S. Lively, and S. J. Eisenreich.
Journal of Great Lakes Research, Vol 7, No 3, p 299-310, 1981. 4 Fig, 4 Tab, 47 Ref.

Descriptors: *Sedimentation rates, *Lake sediments, Lakes, *Lake Superior, Lake basins, *Trace metals, Shores, Storms, Erosion, Sediment cores, *Cores, Sediment sampler.

Sedimentation rates in Lake Superior ranged from 0.01 to 0.32 cm per year as determined by Pb210 geochronology of 17 sediment box cores taken in representative locations. The western arm of the lake had moderate to high sedimentation rates (0.05-0.11 cm per year), caused by shoreline erosion and resuspension of nearshore sediments. Marginal bays adjacent to the lake had the highest rates (>0.15 cm per year). Open lake regions adjacent to marginal bays had slightly lower rates (0.07-0.19 cm per year). Lowest sedimentation rates (0.01-0.03 cm per year) were in the central basins, which are isolated from sediment sources. Anomalies in Pb210 profiles in the southern and southeastern lake correspondended with severe storms in 1905, 1916-1918, and 1940, the severest storm of the century. These sediment disturbances were produced by resuspension of nearshore and shoal top sediments. Pb210 flux rates range from 0.2-10.0 dpm per sq cm per year, higher than those reported for other lakes. Possible reasons for this are: (1) higher atmospheric deposition rates from uranium bearing rocks or (2) samples collected in shore regions in this study. (Cassar-FRC)

NUTRIENT AND HEAVY METAL TRANSPORT CAPABILITIES OF SEDIMENT IN THE SOUTHWESTERN UNITED STATES,
New Mexico Univ., Albuquerque. Dept. of Biology.
J. R. Gosz, C. S. White, and P. F. Ffolliott.
Water Resources Bulletin, Vol 16, No 5, p 927-933, October, 1980. 4 Fig, 4 Tab, 13 Ref.

Descriptors: *Sediment transport, *Chemical analysis, *Phosphorus, Trace metals, *Heavy metals, *Nutrients, Watersheds, Geology, Pine trees, New Mexico, Arizona, Solute transport, Soil types, Vegetation, Comparison studies.

This paper reports on a preliminary test of the hypothesis that sediment of a given size classification derived from small watersheds of uniform bedrock and a single vegetation type would have a uniform nutrient and heavy metal transport capacity. A comparison was made of samples from ponderosa pine communities growing on basalt, sandstone, limestone, and granite bedrock, and a comparison was made between a ponderosa pine community and a mixed conifer community on basalt bedrock. Analyses of acid-digestable and extractable nutrients showed differences for sediments derived from ponderosa pine forests in the Southwest on different geologies. These differences were similar for soil, stream bank, and stream channel material from a given site. Suspended sediment collections had nutrient concentrations similar to those of stream channel collections. Different vegetation on a given geology affected primarily the organic matter content, cation exchange capacity, total phosphorus, and levels of extractable nutrients in sediment. With additional work on other vegetation associations and a larger number of examples for a given bedrock, this approach may allow reasonable estimates of element loss from watersheds, knowing only bedrock composition, vegetation association, and sediment output. Descriptors: *Sedimentation, *Mathematical models, *Sediment discharge, *Reservoirs, Mathematical studies, Model studies, Statistical models, Statistical methods, Markov process, Sediment load, Sediment distribution, Sediment yield.

The volume of sediment accumulated in a reservoir over a period of years was considered as the sum of the annual sediment volumes for those years, which are obtained using the correlation between sediment discharge and river discharge and are treated as random variables in a statistical analysis. If longer records of stream flows are available, the relationship between sediment load and river discharge may function as a transformation of variables by which the distribution of sediment discharge (S) is transferred from the distribution of river discharge (Q). The relationship between these variables may also serve as a data generating system which provides a sediment S-sequence of the same length as the river discharge Q-sequence. Assuming the S- and Q-sequences follow a log-normal distribution, the mean and variance of the sediment volume accumulated in the design was applied to case studies at Kang Khoi on the Pasak River and at Nawarat Bridge on the Ping River, good agreement between values of the S- and Q-sequences were found. RESERVOIR SEDIMENTATION AND ITS CAUSES IN ILLINOIS,
Illinois State Water Survey, Urbana.
J. B. Stall, and M. T. Lee.
Water Resources Bulletin, Vol 16, No 5, p 874-880, October, 1980. 6 Fig, 6 Tab, 10 Ref.

Descriptors: *Reservoirs, *Sedimentation, Sedimentation rates, Reservoir silting, Watersheds, Soil erosion, Lakes, *Illinois, Model studies, Computers.

The objectives of this paper were to provide for the state of Illinois a summary of the rates of destruction of impounding reservoirs by sediment deposition; to illustrate the use of the Universal Soil Loss Equation (USLE) to calculate soil losses from every farmer's field, from subwatersheds, and from an entire drainage area; to illustrate a sediment source map for an entire watershed; and to show how this sediment source map can be used to identify areas of the watershed where soil losses are excessive. Detailed surveys were made on 107 lakes. A generalized graph allows annual reservoir capacity loss in percent to be estimated based on size of watershed, lake capacity and watershed ratio. For the 258 square miles of land on the watershed of Lake Springfield, complete soil maps were measured using a graphic digitizer. A computer readable map was produced. The USLE was solved to provide upland soil losses for each area of the watershed. Average watershed soil loss was 3.96 tons per acre per year, and 24% of this was delivered to the lake, meaning that a representative lake in Illinois would have a normal life of 161 years. BANK FAILURE AND EROSION ON THE OHIO RIVER,
Louisville Univ., KY. Dept. of Civil Engineering.
D. J. Hagerty, M. F. Spoor, and C. R. Ullrich.
Engineering Geology, Vol 17, No 3, p 141-158, 1981. 9 Fig, 3 Tab, 6 Ref.

Descriptors: *Bank erosion, *Mechanical failure, *Erosion, River flow, *Ohio River, Navigation,

Locks, Water level, Boats, Washouts, Infiltration, Land use, Alluvial deposits, Drainage.

Large numbers of riparian landowners along the Ohio River have complained that bank failures and erosion have been caused and/or accelerated by the existence of navigation-aid structures as well as prop turbulence and wave-related erosion by river traffic. Therefore studies were conducted on failure and erosion as well as on river regulation mechanisms. Paintings, photographs and reports revealed a history of significant bank erosion on the Ohio River for more than 150 years, primarily related to storms and high water periods. Construction of larger dams and locks raised retained water levels in some areas. No correlation was found between the ages of given pools and the apparent severity of erosion. During low to moderate flows water levels in the upstream reaches of navigation pools fluctuate somewhat more frequently than water levels immediately upstream from the dams, but fluctuations are smaller than those which occurred prior to dam construction. Based on reconnaissance surveys, bank failure and erosion were found to be a function of bank materials, topography, land use, river morphology and weather cycles. The phenomena are episodic and complex. The principal erosion mechanism appears to be bank material removal by current tractive forces during flood events and internal erosion of bank materials by bank discharge following floods. Landslides at several sites were triggered by periods of greater than average precipitation. Changes in drainage and land use which increase infiltration behind river banks could accelerate this internal erosion mechanism. No significant correlation was found between boat traffic level and bank erosion, but significant site-specific effects are possible. (Carroll-FRC)

EROSION AND SEDIMENTATION IN THE KENAI RIVER, ALASKA,
Geological Survey, Laguna Niguel, CA. Water Resources Div.
K. M. Scott.
Available from Supt. of Documents, GPO, Washington, DC 20402, Price, $3.25. Geological Survey Professional Paper 1235, 1982. 35 p, 19 Fig, 5 Tab, 53 Ref.

Descriptors: *Streams, *Channel erosion, *Bank erosion, *Sedimentation, Watersheds, Flow characteristics, Snowmelt, Floods, Bed load, Gravel, Vegetation effects, Fisheries, Salmon, Hydrographs, Aerial photography, *Alaska, *Kenai River.

The Kenai River is the most important freshwater fishery in Alaska. The flow regime is characterized by high summer flow of glacial meltwater and periodic flooding caused by sudden releases of glacier-dammed lakes in the headwaters. Every part of the stream is a known or potential salmon-spawning site. The stream channel is underfit, attributed to regional glacial recession and drainage changes, and locally is entrenched in response to geologically recent changes in base level. Throughout the central section of the river the channel is armored, a condition with implications for the ability of this section of channel to support the spawning and rearing of salmon. The entrenched section of the channel has been stable since 1951. Bank erosion is active both upstream and downstream from the entrenched channel, however. Although erosion rates have been generally constant since 1951, evidence suggests a possible recent decrease in bank stability that may be related to changes in river use. As population and recreation use increases, development can pose a hazard to the productivity of the stream through increased suspended-sediment concentration resulting directly from construction and, with greater potential for long-term impact, indirectly from bank erosion. A short-term hazard to both stream and developments is the cutoff of meander loops, the risk of which is increased by canals and boat slips cut in the surface layer of cohesive, erosion-resistant sediment on the flood plain within nonentrenched meander loops. A long-term hazard is an increase in bank erosion rates resulting from loss of vegetation on the high (up to 70 feet) cutbacks of entrenched and partially entrenched section. (USGS)

ANASTOMOSED RIVER DEPOSITS: MODERN AND ANCIENT EXAMPLES IN ALBERTA, CANADA,
Calgary Univ. (Alberta). Dept. of Geography.
D. G. Smith, and P. E. Putnam.
Canadian Journal of Earth Sciences, Vol 17, No 10, p 1396-1406, October, 1980. 7 Fig, 1 Tab, 41 Ref.

Descriptors: *River beds, *Sediments, *Sedimentation, River basins, Wetlands, Channel flow, Aggrading rivers, Anastomosed deposits, *Canada, Alexandra River, Alluvial deposits, *Braided streams, Alberta, British Columbia.

Anastomosis is suggested as an alternative fluvial system to those of deltaic, braided, and meandering for the deposition of some thick fluvial deposits located in Alberta and British Columbia. An anastomosed fluvial system is a low energy complex of several interconnected channels of variable sinuosity crossing a wetland and forming many elongate vegetated islands. The causal mechanism is either a rising local base level control downriver, or a subsidence of the depocentre relative to a downriver reach. Modern and ancient examples of anastomosis are described to provide a basic depositional framework. One modern example is the lower reach of the Alexandra River in Banff Park. Ancient examples occur in east central Alberta and southwest Saskatchewan. Anastomosed systems have only recently been recognized as a unique fluvial style related to specific causal conditions. Much more field work on modern examples is necessary. (Small-FRC)

HOW RAIN INTENSITY AFFECTS INTERRILL EROSION,
Science and Education Administration, Oxford, MS. Sedimentation Lab.
L. D. Meyer.
Transactions of the ASAE, Vol 24, No 6, p 1472-1475, November/December, 1981. 3 Fig, 2 Tab, 18 Ref.

Descriptors: *Rain intensity, *Erosion, *Sediment transport, Clays, Soil types, *Rill erosion, Soil erosion, Interrill erosion, Runoff, Cropland, Sediment yield, Cultivation, Vegetation effects.

Artificial rainfall was applied to crop row side slopes in fields to determine the effects of rain intensity on interrill erosion. Study sites were farm fields in Mississippi and Iowa. Different soils and cropping conditions were used in the investigation. An equation, $E = aI$ to the b power, where E = erosion rate, a = coefficient of best fit, I = rain intensity, and b = exponent of best fit, was suitable for a wide range of soils and cropping conditions. The exponent b decreased from 2.0 for soils of low clay content to 1.6 for soils with 50% clay. This showed that the influence of rain intensity on erosion was greater for low-clay soils than for high-clay soils, possibly because of greater soil cohesiveness in the higher-clay soils. The equation $E = cI$ squared, where c = ratio of coefficients, fit the data for high clay soils. The relative interrill erodibilities of the different soils or the relative erosion from different cropping conditions are quantitatively indicated by c. (Cassar-FRC)

A KINETIC MODEL FOR SURFACE MINE SEDIMENT YIELD,
Science and Education Administration, Fort Collins, CO.
R. E. Smith.
Transactions of the ASAE, Vol 24, No 6, p 1508-1514, November/December, 1981. 11 Fig, 20 Ref.

Descriptors: *Sediment transport, *Surface runoff, *Strip mines, Sediment yield, *Model studies, *Colorado, *Watershed management, Erosion, Sedimentation ponds, Ponds, Hydrologic models, Runoff, Snowmelt, Land treatment, Vegetation effects, Simulation.

A general watershed runoff and sediment transport model, KINEROS, is given for managing watersheds. Although the model can be applied to a wide range of situations from small urban regions to agricultural watersheds, this paper features its application to a watershed disturbed by surface mining. The major components are infiltration, surface water flow, channel flow, sediment transport, and pond storage. The model is applied to a steep 22-ha watershed established in a strip mine region in western Colorado. Measured and simulated runoff from two summer storms in August 1979 agreed well. Simulation of the April 19, 1979, snowmelt did not produce results comparable to the observed sediment concentrations. Modeling of a sedimentation pond, not yet in operation, indicated the effects of different treatments of surrounding land, such as terraces and vegetative cover. More suitable transport equations are needed for predicting sediment transport on steep watersheds with fine sediments. (Cassar-FRC)

MATHEMATICAL SIMULATION OF SEDIMENT MOVEMENT IN STREAMS,
Hydraulics Research Station, Wallingford (England).
R. Bettess, and W. R. White.
Proceedings of the Institution of Civil Engineers, Part 2: Research and Theory, Vol 71, No 3, p 879-892, September, 1981. 4 Fig, 14 Ref.

Descriptors: *Sediment transport, *River beds, Sediment sorting, *Model studies, Bed load, Milburn Dam, *Nebraska, *Middle Loup River.

A model for sediment movement in streams was developed and used to predict changes in bed loads and changes in the composition of the bed materials over periods of several years. The model is one-dimensional and time-dependent, and all river properties such as discharge, stage, and bed level, depend only on two variables: the distance along the river and the time. Satisfactory results were obtained when the model was applied to two problems: a laboratory flume test and a field test of a 5200 m reach of the Middle Loup River downstream of Milburn Dam, Nebraska. The observed and calculated bed levels directly downstream of the dam in 1964 were about 1 m less than the original 1961 bed level. (Cassar-FRC)

Ground Water, Vol 20, No 1, p 5-11, 1982. 12 Fig, 10 Ref.

Descriptors: *Beach erosion, *Great Lakes, *Artesian pressure, *Groundwater movement, *Slope stability, Erosion, Bank erosion, Slope degradation, Artesian flow, Confined aquifers, Shore protection, Piezometers, Pore pressure, Geologic fractures, Canada, United States.

Receding shorelines along the Great Lakes have resulted in millions of dollars worth of property damage in the United States and Canada. Various projects that have investigated this erosion problem have shown that wave action at the base of the bluff is the main cause of bluff-top retreat. A study of the physical processes which cause bluff erosion

LIBRARY U. OF I. - URBANA CHAMPAIGN

was undertaken with special focus on the role of groundwater in bluff stability. In one section of the Lake Michigan shoreline, an annual bluff-top recession of 9 to 10 m was recorded that was not related to toe erosion. Heads were measured in 25 piezometers at the site and a complex groundwater flow system was found. A glacial sand unit under artesian pressure was detected 5 m above the toe bluff while another 'perched' system existed in a fractured till unit at the top of the bluff. Fluctuations of up to 13 m/year which were recorded in the lower sand unit significantly affected bluff stability. Field data of pore pressures and calculations of the effective strength values of soil units were utilized in slope stability determinations to estimate safety factors. (Geiger-FRC)

DISTRIBUTION OF CLAY MINERALS AND THEIR DIAGENESIS IN THE SEDIMENTS OF LAKE EDKU,
Alexandria Univ. (Egypt). Dept. of Oceanography.
M. A. El Sabrouti, and A. A. Sokkary.
Marine Geology, Vol 45, No 1/2, p M15-M21, 1982. 3 Fig, 1 Tab, 14 Ref.

Descriptors: *Diagenesis, *Clays, *Sediments, Shallow lakes, *Lake sediments, Bottom sediments, Organic acids, Organic matter, Montmorillonite, Kaolinite, Illite, Nile Delta, *Lake Edku, Lagoons, Egypt.

Analyses of seven core samples from bottom sediments in Lake Edku, west of the Nile Delta, indicated that these sediments were derived from the Nile River, not from wind-transported sediments. This coastal lagoon varies in depth from 10 to 140 cm and receives inflow from the Mediterranean during dry periods. The major contituent of the sediments was montmorillonite, 47-80%. Illite and kaolinite were present at 7-37% and 6-29%. The proportion of montmorillonite increased and the proportion of illite decreased with increasing sediment depth. Kaolinite also decreased with depth, but to a smaller degree, 4-12%. It is believed that some of the illite was diagenetically changed to montmorillonite through the action of organic acids formed through decomposition of organic matter in the bottom sediments. HYSTERESIS IN RELATIONSHIPS BETWEEN DISCHARGE AND WATER CHEMISTRY IN THE FRASER RIVER BASIN, BRITISH COLUMBIA,
Department of the Environment, Vancouver (British Columbia).
P. H. Whitfield, and H. Schreier.
Limnology and Oceanography, Vol 26, No 6, p 1179-1182, 1981. 5 Fig, 1 Tab, 6 Ref.

Descriptors: *Water chemistry, *Hysteresis, *Fraser River, Rivers, Sampling, Sample preparation, Water sampling, Monitoring, Water quality, Discharge measurement, Load distribution, *British Columbia, *Streamflow-water quality relations.

Analysis of water samples taken from the Fraser River showed a general hysteresis in the discharge-concentration relationship recurring from year to year, with an overall pattern which was remarkably consistent over a 4 year period. The shape of the hysteresis changed more dramatically from one sampling station to another than from year to year. If the hysteresis were symmetrical the overall regression equation would balance the seasonal over- and under-predictions. However, most of the loops are asymmetrical, and yearly predictions thus become more complex and less accurate. Many properties showed hysteresis development when plotted against discharge. Differences were noted not only in the shape of the hysteresis but also in the direction. At some stations the loop developed in a clockwise direction, while in others it was counterclockwise, and in some it crossed over. Several different processes influence the development and shape of the hysteresis, and thus it is not possible to develop a universal model for predicting loadings in the entire river basin. Different rates of nutrient cycling, biological uptake, storage-discharge relationships, and factors relating to climatic and cyclic events are in part responsible for creating a hysteresis. To avoid statistical problems related to serial correlations and hysteresis a complex sampling design is needed, where samples are collected at equal spaces in time and at equal increases in discharge volume. Samples need to be taken often enough to include individual events of high discharge. (Baker-FRC)

WATER CHEMISTRY OF THE ILLINOIS WATERWAY,
Illinois State Water Survey Div., Champaign.
V. Kothandaraman, R. A. Sinclair, and R. L. Evans.
Circular 147, 1981. 23 p, 6 Fig, 15 Tab, 12 Ref.

Descriptors: *Chemical analysis, Physical analysis Water sampling, Streams, *Waterways, Water quality, Data collections, Alkalinity, Dissolved oxygen, Chlorides, Suspended solids, Water temperature, Orthophosphates, Ammonium compounds, Nitrogen compounds, Nitrates, Fluctuations, *Baseline studies, *Lake Michigan, *Water diversion, *Illinois waterway.

A two-year field sampling effort was undertaken by the Illinois State Water Survey to develop baseline water chemistry data prior to increased diversions of Lake Michigan waters into the Illinois Waterway, and to assess the probable impact of the diverted waters on the water chemistry of the waterway. Physical and chemical water quality characteristics are summarized from data obtained at 28 sampling locations established at 10-mile intervals and covering about 270 miles of the waterway. Observations and samples were used to determine temperature, dissolved oxygen (DO), turbidity, pH alkalinity, hardness, chlorides, total solids, suspended solids, orthophosphate-phosphorus, total phosphate-phosphorus, ammonium-nitrogen, and nitrate nitrogen. The waterway was divided into seven reaches and data within each were combined. The Illinois Waterway is high in alkalinity, total solids, and hardness. The pH samples varied from 7.6 to 9.3---within established limits of the Illinois Pollution Control Board. Alkalinity and hardness increased as the river flowed downstream. Ammonia concentrations were higher in the upper reaches of the river as were DO levels. Long-term average mineral and nutrient transports at three USGS gaging stations were made by the flow duration curve method. Nitrate flux at the stations varied from 8.88 to 13.83 lbs/ac/yr and are in the mid-range of values reported for other Illinois streams. Phosphorus loads varied from 1.20 to 2.96 lbs/ac/yr which are several times higher than the values reported for other Illinois streams. (Atkins-Omniplan)

A PHYSICAL REASON FOR HIGHER PH OF TROPICAL RAINWATER,
Meteorological Office, Poona (India).
A. K. Mukherjee, and K. Nand.
Mausam, Vol 32, No 3, p 231-236, July, 1981. 3 Fig, 4 Tab, 8 Ref.

Descriptors: *Rain, *Carbon dioxide, *Hydrogen ion concentration, *India, Tropical regions, Monsoons, Solubility, Temperature, Air temperature.

Differences in pH of rainwater between northern European countries and tropical countries are explained with respect to the solubility of carbon dioxide at different temperatures. The theoretically calculated pH at 20 C is 5.65, based on the assumption that dissolved carbon dioxide is in equilibrium with atmospheric CO2. The pH of rainwater in India is close to neutral, 7.0. In colder European countries the solubility of CO2 in water is about 1.5 times that in the tropics. In addition, the dissolution rate of CO2 in rainwater is about 1.5 times higher in the colder countries. In the tropics the higher atmospheric temperature, lower solubility and dissolution rate of CO2, and the rapid cloud formation and precipitation result in a higher pH. (Cassar-FRC)
W82-04669

GEOCHEMISTRY OF THERMAL AND MINERAL WATERS IN THE CASCADE MOUNTAINS OF WESTERN NORTH AMERICA,
Oregon Water Resources Dept., Salem.
L. S. Forcella.
Ground Water, Vol 20, No 1, p 39-47, 1982. 5 Fig, 1 Tab, 22 Ref.

Descriptors: *Thermal springs, *Thermal properties, *Chemical properties, *Mineral springs, Hydrogen ion concentration, Ions, Water properties, Geohydrologic units, Geohydrology, Geothermal studies, Geothermal resources, Mineral water, Geophysics, *Cascade Mountains, Washington, Oregon.

The chemistry of thermal and mineral waters in the Cascade Mountains was examined as a basis for future comparisons with other hydrothermal systems and for future development of geothermal resources. The thermal and mineral waters from the Cascades may be classified into three chemically distinct groups. Group 1 exhibits a neutral pH, an average total dissolved solids (TDS) value of 2650 ppm, and dominant Na and Cl ions. Group 1 waters issue from the geothermally attractive Central Cascades and were probably in prolonged contact with Eocene marine sediments during the Mesozoic era. Group 2 waters are fumarolic acid-sulfate waters from the vents of Mt. Lassen, Newberry Crater and Mt. Hood. Basic brines discharge from the base of Mt. Lassen and Mt. Hood. The Group 3 waters are characterized by chemical inhomogeneity between different points of discharge. Dominant ions are Cl, Na, HCO3, and SO4 and the pH ranges from 6.2 to 9.7. The thermal waters of the Cascade Province have been subject to various degrees of mixing and proximity to heat which might account for the chemical differences. (Geiger-FRC)

ISOTOPE GEOCHEMISTRY OF WATER IN GULF COAST SALT DOMES,
Arizona State Univ., Tempe. Dept. of Geology.
L. P. Knauth, M. B. Kumar, and J. D. Martinez.
Journal of Geophysical Research, Vol 85, No B9, p 4863-4871, September 10, 1980. 2 Fig, 1 Tab, 32 Ref.

Descriptors: *Geochemistry, *Isotope studies, *Salt domes, Meteoric water, Chemical composition, Oxygen, Hydrogen, Salt mines, Saline water, Groundwater, Louisiana, *Gulf of Mexico, Weeks Island, Jefferson Island, Belle Isle.

Water has occasionally been found to enter newly excavated chambers in salt domes along the northern coast of the Gulf of Mexico from ceiling drips,

wall seeps, and exploratory boreholes. An understanding of the origin of this water is extremely important in evaluating the suitability of salt domes as isolation sites for nuclear waste proucts. Possible origins include connate waters that have been in the salt since deposition and waters external to the dome which have somehow penetrated or become incorporated into the salt. The hydrogen and oxygen isotopic composition of water samples collected from salt mines on Weeks Island, Jefferson Island, and Belle Isle in southern Louisiana were analyzed in an effort to determine the origin of the water. Two samples were found to be isotopically similar to local surface waters and clearly of meteoric origin. All of the other samples were too enriched in oxygen-18 to be meteoric waters. Water derived from active leaks in three mines on Weeks Island was too enriched in oxygen-18 and too depleted in D to be connate ocean water or evaporite connate water trapped in the salt. It is unlikely that the water originated from the dehydration of gypsum or that isotopic exchange with anhydrite is responsible for the oxygen-18 enrichments. It is concluded that the nonmeteoric waters are saline formation waters which have become incorporated in the salt. The observed oxygen-18 enrichments suggests that the formation waters were incorporated during diapiric rise of salt at a depth of 3 to 4 kilometers and have been trapped within the salt for between 10 and 13 million years. The presence of limited amounts of such trapped formation water in the salt within salt domes will have to be considered when planning radioactive waste storage in salt domes. (Carroll-FRC)

SURVIVAL AND HETEROTROPHIC ACTIVITIES OF FRASER RIVER AND STRAIT OF GEORGIA BACTERIOPLANKTON WITHIN THE FRASER RIVER PLUME,
Simon Fraser Univ., Burnaby (British Columbia). Dept. of Biological Sciences.
M. Valdes, and L. J. Albright.
Marine Biology (Berlin), Vol 64, No 3, p 231-234, 1981. 9 Fig, 3 Tab, 40 Ref.

Descriptors: *Nutrients, *Plumes, Rivers, Carbon, Nitrates, Phosphorus, *Bacteria, *Estuaries, Plankton, Fraser River, Strait of Georgia, *British Columbia, Canada.

Subsurface samples of water were taken from various locations in the Fraser River, its plume and the Strait of Georgia and use for experimental purposes within 1 hr of collection. The majority of the autochthonous heterotrophic bacterioplankton of the lower Fraser River appeared to be killed when placed in marine water taken from the Strait of Georgia. However, their marine counterparts with Strait of eorgia surface water remained viable when treated with Fraser River water. Within the plume water a stimulation of glucose heterotrophic activity occurred within the salinity range of about 3-18 0/00. The plume water itself arises naturally when the freshwater of the Fraser River mixes with the marine water of the Strait of Georgia. This increase in bacterioplankton activity may be a result of a better nutrient environment within plume water as compared to either parent water. It is noted that there is a well distributed and relatively high inorganic carbon, nitrate and phosphorus content in the plume water, which makes it more nutritionally complete for acteria than either of the other waters. THE EFFECT OF DRIED AND CRACKED SEDIMENT ON THE AVAILABILITY OF PHOSPHORUS IN A COASTAL LAGOON,
Universidad Nacional Autonoma de Mexico, Mexico City. Inst. de Biologia.
V. Arenas, and G. De La Lanza.
Estuaries, Vol 4, No 3, p 206-212, 1981. 3 Fig, 2 Tab, 16 Ref.

Descriptors: *Lagoons, *Phosphorus, Nutrients, Estuaries, Estuarine environment, Cycling nutrients, *Mexico, Coastal waters, Water level, Aquatic plants, Sediments, *Caimanero Lagoon, Dry sediment.

The effect of dried and cracked sediments on the availability of nutrients such as phosphorus in coastal ecosystems was investigated. The study area was the Caimanero Lagoon, which is subject to alternate periods of low water and flooding. In times of low water, more than 70% of the lagoon area is dry, cracked and colonized by halophytes to variable proportions. Mineralization of organic matter occurs during these dry times and reavailability of phosphorus takes place to a great extent. The amount of soluble organic matter also increased during the dry seasons. It was established that the sedimentary drying and cracking process contributed significantly to estuarine productivity, probably due to the ability of algae to utilize the phosphorus from organic sources. OREGON COASTAL SALT MARSH UPPER LIMITS AND TIDAL DATUMS,
Oregon State Univ., Corvallis.
R. E. Frenkel, H. P. Eilers, and C. A. Jefferson.
Estuaries, Vol 4, No 3, p 198-205, 1981. 4 Fig, 3 Tab, 18 Ref.

Descriptors: *Salt marshes, Coastal zone management, Wetlands, *Tidal marshes, Marshes, *Oregon, *Coastal marshes, *Saline-freshwater interfaces, Saline water intrusion.

Independent surveys were made of three coastal salt marshes to determine the upper limit of marsh. The areas of study included South Beach marsh of the Yaquina River estuary, Drift Creek marsh of the Alsea River estuary, and Bandon marsh of the Coquille River estuary. Primary tidal data are relatively infrequent for the Oregon Coast. Of the marshes studied, only South Beach had dependable data. The relation of tidal datum planes to National Geodetic Vertical Datum (NGVD) was not readily available and was determined from vertical control data for bench marks. A transition zone between marsh and upland was identified by strong dominance of Potentilla pacifica and the presence of Achillea millefolium, Angelica lucida, Aster subspicatus, Oenanthe sarmentosa, Trifolium wormskjoldii, and Vicia gigantea. The mean elevation of the lower boundary of the transition zone was 1.38 meters above NGVD and the upper boundary of the transition zone was 1.54 meters above NGVD. The relation of the upper limit of marsh to tidal datums varied with marsh. The mean elevation of the upper and lower limit of the transition zone was 0.58 meters above MHW and 0.36 meters above MHW, respectively. Two teams of biologists using the same biological criteria for defining the upper limit of marsh independently agreed on the elevational position of the upper limit of marsh. Additional research on defining the upper limit of coastal marsh is needed.

NUTRIENT MASS BALANCES FOR THE WATERSHED, HEADWATERS INTERTIDAL ZONE, AND BASIN OF THE RHODE RIVER ESTUARY,
Chesapeake Bay Center for Environmental Studies, Edgewater, MD.
D. L. Correll.
Limnology and Oceanography, Vol 26, No 6, p 1142-1149, 1981. 6 Fig, 1 Tab, 17 Ref.

Descriptors: *Estuaries, *Nutrients, Nutrient removal, *Rhode River Estuary, Maryland, Rivers, Cycling nutrients, Organic matter, Nitrogen, Phosphorus, Seasonal variation, Path of pollutants.

Measurements were made of the dynamics of nitrogen, phosphorus, and organic matter content in the basin, headwaters, intertidal zone and watershed of the Rhode River Estuary. Inputs from precipitation and both surface and groundwater runoff were measured continuously, as well as the tidal flux between the intetidal zone and the main estuarine, open water basin, for a 13-month period. The watershed is dominated by agriculture and secondary successional vegetation, 88 ha of todal marshes and mudflats, and an estuarine open water basin. Less organic matter moved out to the estuary than was discharged into the intertidal zone from the watersheds and deposited in precipitation. Only 1.9 tons of the 2.7 tons of phosphorus discharged from the uplands into the intertidal zone moved into the estuary. In most instances a high discharge of phosphorus from the watersheds was followed in a week or two by a high discharge into the estuary from the intertidal zone. A significantly lower fraction of the total phosphorus moving into the estuary was made up of orthophosphate than had been anticipated based on the amount of orthophosphate moving from the watershed. Of the 10 tons of nitrogen discharged from the watershed into the intertidal zone, only 7.4 tons moved into the estuary. Thus overall removal and storage of nutrients from land runoff by the intertidal zone is apparent. Only when runoff was high due to storms were some of the stored nutrients flushed from the intertidal zone. (Baker-FRC)

VERTICAL MIXING AND PHOTOSYNTHETIC CAPACITY OF ESTUARINE PHYTOPLANKTON (MELANGE VERTICAL ET CAPACITE PHOTOSYNTHETIQUE DU PHYTOPLANCTON ESTUARIEN (ESTUAIRE DU SAINT-LAURENT)),
Laval Univ., Quebec. Dept. de Biologie.
S. Demers, and L. Legendre.
Marine Biology (Berlin), Vol 64, No 3, p 243-250, 1981. 5 Fig, 45 Ref. English summary.

Descriptors: *Estuaries, *Phytoplankton, Vertical distribution, *St. Lawrence Estuary, Vertical distribution, Chlorophyll, Photosynthesis.

Water samples were collected hourly for 167 hours in August of 1975 at an anchor station in the Middle Estuary of the St. Lawrence River, Canada. These samples served as a time series for measuring chlorophyll a, photosynthetic capacity and many physical parameters. Sampling was conducted during the transition from neap to spring tides. Variations in chlorophyll a, both long and short-term, are coupled with the advection of water masses, which in turn depends on the tidal currents. The chlorophyll a concentration of the cells is also influenced by the vertical mixing, as it modifies the physiological state of the phytoplankton. Periodicities were also noted in the photosynthetic capacity, suggesting that the phytoplankton of this area have a homogeneous light history due to strong vertical mixing. The photosynthetic capacity is adapted to the mean light intensity in the mixed layer under these conditions. Semi-monthly variations of the mean light intensity in the mixed layer depend on the semi-monthly variations in the vertical mixing, whereas in the short-term, the variations in mean light intensity in the mixed layer are circadian. Descriptors: *Bacteria, *Sulfates, *Sediments, *Salt marshes, Sulfides, Sulfur bacteria, Molybdates, Fluoroacetates, Oxidation, Marine sediments, Marshes, Estuarine environment, Wetlands, Lake sediments, *England, Ray Creek, Colne Point Marsh, United Kingdom.

Two types of sulfate-reducing bacteria, one oxidizing acetate and one probably oxidizing hydrogen, were found in the salt marsh sediments of Ray Creek, Colne Point Marsh, United Kingdom. Acetate oxidation was partially inhibited by addition of fluoroacetate, a known inhibitor of acetate metabolism. Molybdate completely inhibited acetate oxidation. It apparently acts by suppressing adenosine triphosphate sulfurylase, common to both groups of bacteria. Acetate metabolism in freshwater pond sediments in the absence of sulfate was not affected by molybdate but was inhibited by fluoroacetate. Acetate was oxidized to carbon dioxide, not to methane. Canadian Journal of Zoology, Vol 59, No 12, December, 1981. 3 Fig, 3 Tab, 29 Ref. English summary.

Descriptors: *Estuarine environment, *Species composition, *Benthic fauna, Silt, Flow velocity, *St Lawrence River, Water currents, Water depth, Rivers, Species diversity, *Spatial distribution.

To study the spatial variability of the faunal characteristics and numbers and relate them to the abiotic factors prevailing at various locations, benthic samples were collected with a Ponar bucket at 33 locations on a transect of the upper St. Lawrence estuary. Data were simultaneously obtained on the physicochemical characteristics of the water, water depth, silt content of the surface sediments, and current speed. The principal taxonomic groups represented were oligochaetes (34.4%), hirudinea (4.9%), gastropoda (38.1%), sphaeriidae (19.6%) and chironomids. The physico-chemical characteristics of the water were fairly stable. The most abundant species followed a definite zonation, but no species was truly typical of any one habitat. Depth, percentage of silt, and current velocity, in decreasing order, affected the structure of the benthic associations. The diversity was independent of these factors, but the organism density, number of taxa, and equitability were all significantly correlated with the percentage of silt. (Carroll-FRC)

EFFECT OF RIVER DISCHARGE ON THE DISTRIBUTION PATTERN OF DISSOLVED CONSTITUENTS IN THE GAMO ESTUARY, MIYAGI PREFECTURE,
Tohoku Univ., Sendai (Japan). Biological Inst.
E. Kikuchi, and Y. Kurihara.
Japanese Journal of Limnology, Vol 42, No 2, p 100-107, 1981. 7 Fig, 1 Tab, 7 Ref.

Descriptors: *Wastewater pollution, *Dissolved solids, *Phytoplankton, *Estuaries, *Gamo Estuary, Nanakita River, *Japan, Rivers, Nutrients, Nitrates, Chlorides, Phosphates, Ammonium, Dissolved oxygen, Oxygen, Eutrophication, Diatoms, Cytocella, Ciliates, Mesodinium, Salt wedge estuaries, Saline-freshwater interfaces, Sendai Bay.

Chlorinity, dissolved inorganic nitrogen, phosphate, and dissolved oxygen were measured at 7 sites in the Gamo estuary, Japan, a salt wedge estuary highly polluted with domestic sewage. A weir is located about 4.2 km upstream from the mouth. Sampling sites were located from the mouth to 4 km upstream and at different depths from the surface to the bottom, which ranged from 1 m deep at the mouth to 5 m deep in a trough. Ammonium and phosphate concentrations increased with distance upstream, and dissolved oxygen decreased with distance upstream. Levels of ammonium and phosphate increased with depth. Dissolved oxygen concentrations decreased with depth, reaching zero at the bottom of a trough. These results indicate that the deeper water was trapped in basins by shallow sills for long periods. Nitrate concentrations were higher in the fresh surface water than in the saline bottom water. The effect of the tide on the dissolved constituents was almost negligible in the estuary except near the mouth. In the brackish surface water dissolved oxygen levels were high, and ammonium, nitrate, and phosphate levels were very low. A phytoplankton bloom at low flow in summer was dominated by diatoms (Cytocella) in the fresh surface water and ciliates (Mesodinium) in the saline water. (Cassar-FRC)

SALINITY INTRUSION IN ESTUARIES,
Institute of Oceanographic Sciences, Merseyside (England).
D. Prandle.
Journal of Physical Oceanography, Vol 11, No 10, p 1311-1324, October, 1981. 7 Fig, 2 Tab, 30 Ref.

Descriptors: *Saline water intrusion, *Tidal effects, *Mixing, *Estuaries, Rivers, Model studies, Salinity, Fate of pollution, Dispersion coefficient.

One-dimensional solutions were examined for thd degree of saline water intrusion into estuaries of different shapes. These solutions emphasize the importance of the rate of change of cross-sectional area in determining salinity distribution. The salinity distribution was shown to be highly dependent on the dimensionless parameter VI, which equals U1 x X1 divided by D, where U1 = velocity of freshwater flow at position X1, the point where the salinity of the estuary equals the oceanic value, and D = longitudinal dispersion coefficient. The predicted and observed salinity distributions were compared for 8 estuaries. The values of D were within the range of 50-500 sq m per sec for 6 estuaries (Hudson, Potomac, Delaware, Bristol Channel, Thames, and St. Lawrence). Since salinity distribution is highly sensitive to the specified value of D, the one-dimensional, time-averaged approach may be limited. Attempts to derive a more rational dimensionless form for the longitudinal dispersion coefficient in terms of gross estuarine parameters were not successful. (Cassar-FRC)

REQUIREMENTS FOR CONTINUOUS AUTOMATIC WATER QUALITY MONITORING IN THE THAMES ESTUARY,
Thames Water Authority, London (England).
A. G. Cockburn, and R. J. Furley.
Water Science and Technology, Vol 13, No 11/12, p 693-698, 1981. 3 Fig, 5 Ref.

Descriptors: *Estuaries, *Water quality, Monitoring, Estuarine environment, Water management, Measuring instruments, *Thames River, Rivers, Water pollution control, Water management, England.

The paper discusses the reason for automatic continuous monitoring on tidal rivers and the requirements of such a system in the Thames Estuary. The Tidal Thames is a well mixed estuary stretching some 140 kilometers from Teddington, through the heart of London, th the North Sea. Prior to 1960 the Tideway was anaerobic and devoid of all fish life for much of its length, but improvements in effluent quality have resulted in minimum average dissolved oxygen concentrations of 30% in recent years and the consequent return of large fish populations. Automatic continuous water quality monitoring should prove an efficient and cost effective management tool in the continuing improvement of the Tidal Thames. Running costs including servicing requirements will be less than those currently incurred by manual sampling and analysis using launches, and the information obtained will be much more complete. Significant storm sewage discharges occur in the uppermost 30 kilometers of the estuary, where dilution is small; these can cause sudden severe depletion in dissolved oxygen and consequent fish mortality. It is possible to alleviate the situation by direct injection of pure oxygen into the river by barges towed to the appropriate locations. For this method to be viable, continuous monitoring, together with appropriate telemetry, is essential to give early warning of deteriorating water quality and proper operational control. Site selection for water quality monitoring programs is absolutely critical. (Baker-FRC)

A SUSPENDED SEDIMENT FRONT IN THE SEVERN ESTUARY,
Institute of Oceanographic Sciences, Taunton (England).
R. Kirby, and W. R. Parker.
Nature (London), Vol 295, No 5848, February, 1982. 5 Fig, 12 Ref.

Descriptors: *Estuaries, *Suspended sediments, Sediments, Salinity, Sedimentation, Estuarine environment, Topography, Coriolis force, Tidal effects, *Severn Estuary, *England.

The structure of the suspended solids field was observed in the Severn Estuary using a free-fall array consisting of two narrow-gap optical turbidity meters, a pressure depth sensor, and occasionally a continuously recording conductivity meter, allowing continuous and rapid vertical profiles to be made from drifting or anchored vessels. The regional spring surface and spring bed distributions show the sediment front as a zone of marked gradient approximately along the axis of the estuary between The Shoots and the Holm Islands, and extending across the inner Bristol Channel to the English coast in the region of Watchet, in Bridgewater Bay. The more turbid water mass lies on the English side of the estuary. On neap tides the regional distribution was similar, although the contrast between surface and bed concentration values is greater. Data plots showed that the sediment front was more prominent on spring than on neap tides and on ebb rather than flood tides. Steeply inclined concentration contours were noted across the gradient zone in the region between The Bridge and a line joining Barry and Burnham. The front may be due to an interaction between the regional and local topography. Coriolis effects and lateral phase differences in tidal elevation across the estuary, which set up secondary water circulation cells in the plane of the cross-section, leading to convergence along the main channel axis. It is concluded that the Severn estuary, while well mixed with regard to salt, shows marked lateral partitioning of suspended sediment, with a stably positioned front forming the junction between the two water masses. SHEET FLOW IN A SALT-MARSH BASIN, NORTH INLET, SOUTH CAROLINA,
Rhode Island Univ., Kingston. Graduate School of Oceanography.
J. L. Miller, and L. R. Gardner.
Estuaries, Vol 4, No 3, p 234-237, 1981. 4 Fig, 13 Ref.

Descriptors: *Laminar flow, *Salt marshes, Stratification, Tidal prism, Water storage, Estuaries, Estuarine environment, Tidal marshes, *South Carolina, North Inlet area, Saline-freshwater interfaces.

This paper evaluates the magnitude of sheet flow in a small marsh basin near North Inlet, South

Carolina by comparing basin storage curves determined by current measurements with a basin storage curve based on direct measurements of marsh topography and hypsometry. The basin is well outlined by terrestrial vegetation. The study indicated that on spring tides, more than 50% of the tidal prism that enters Oyster Landing basin enters as sheet flow over the grassy flats of the marsh. The discharge data also suggest that the storage curve for the basin may be a hystersis loop with separate flood and ebb segments. (Baker-FRC)

SEASONAL CHANGES IN THE DEPTH DISTRIBUTIONS OF INTERSTITIAL SALINITIES IN THE FRASER RIVER ESTUARY, BRITISH COLUMBIA,
Victoria Univ. (British Columbia). Dept. of Biology.
P. M. Chapman.
Estuaries, Vol 4, No 3, p 226-228, 1981. 2 Fig, 11 Ref.

Descriptors: *Sediments, *Interstitial water, *Salinity, *Fraser River estuary, Estuaries, *British Columbia, Estuarine environments, *Seasonal variation, Stratification.

Results of a study of vertical and temporal variations in the interstitial salinities of subtidal estuarine sediments are presented. The study was carried out at six stations in the Fraser River estuary spaced to encompass the whole spectrum from freshwater to salt water regions. Stations were sampled monthly in replicate at four sediment depths, and horizontal and vertical changes in interstitial salinity were recorded. The main pattern of flow in the Fraser River is a constant one of low discharge in winter, medium discharge in autumn, and highest discharge between May and June. Maximal salinities occur over winter and minimal salinities during freshet. The seasonal pattern of interstitial salinities at all stations reflected this trend. Interstitial salinities were conservative and reflected seasonal changes in the salinity of the overlying water. These seasonal changes in interstitial salinity are probably due to diffusion. Definite salinity gradients were present in the sediments, particularly in the mesohaline zone of the estuary, and the magnitude of these gradients changed seasonally. It is suggested that interstitial salinity gradients may be a common feature of estuaries. (Baker-FRC)

Descriptors: *Desalination, *Distillation, *Powerplants, Jeddah, *Saudi Arabia, *Red Sea, Seawater, Boilers, Turbines, Water supply, Water treatment.

The Jeddah IV seawater desalination and power plant was put into operation in Saudi Arabia on October 24, 1981. This is currently the largest such plant in the world, and upon full operation will supply about 220,000 cu m of drinking water per day. It is located on the Red Sea, about 8 km north of the city of Jeddah. It covers an area of 20 hectares and supplies electrical energy as well as water. Five oil-fired boilers produce 605 t/hr of steam which is used to run the turbines and as the desalination starting product. The basic process for desalination is multi-stage flash distillation. Ten desalination sections can be operated independently, at a brine temperature of 112 C. Sulfuric acid is added to prevent the deposition of magnesium hydroxide and calcium carbonate in the evaporator-condenser chambers. The boiler supply and cooling water (43 cu m/sec at full capacity) is collected at 16 m below the sea surface, and prepurified with rakes and band filters. Oil is delivered by tank ship, with sufficient storage capacity on site for 32 days of operation. (Carroll-FRC)

DESIGN, FABRICATION AND START-UP OF A 25,000 GALLONS PER DAY ABSORPTION FREEZING VAPOR COMPRESSION DESALINATION PILOT PLANT.
Concentration Specialists, Inc., Andover, MA.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-220526, Price codes: A04 in paper copy, A01 in microfiche. Report, May, 1981. 63 p, 8 Fig, 1 Tab, 1 Append. 14-34-0001-8502.

Descriptors: *Desalination plant, *Freezing, *Vacuum, *Absorption, Pilot plant, Ice-brine systems, Refrigeration, Electric power demand, Specifications, *Wrightsville Beach, North Carolina, Test facility.

Concentration Specialists, Inc. designed, built, initiated start-up and began operational testing of a 25,000 gallons per day adsorption freezing vapor compression (AFVC) sea water desalination plant at the Office of Water Research and Technology's Test Facility at Wrightsville Beach, North Carolina. The AFVC process is a novel freezing process based upon an absorption cycle powered by a heat pump. The energy savings and lack of corrosion of freezing compared to evaporative processes is a significant feature of this process. The pilot plant was designed to produce 25,000 gallons per day of fresh water while consuming 49 kWh of energy per 1000 gallons of product water. Upon design and fabrication, start-up and operational testing of the pilot plant has shown the need for considerable process and component modification as would be expected with a developmental process. By the end of the contract period, June 1980, the pilot plant produced 8000 gallons per day of product water under non-steady state operating conditions. Equipment modification continues toward increasing plant capacity and achieving steady state production.

Pilot plant studies at the France, demonstrated that ammonia-containing refinery wastewater effluents could be successfully used in cooling towers with addition of chromate corrosion inhibitors and appropirate water treatment. The effluent contained 20-50 mg per liter ammonia, which encouraged biological fouling. This was controlled by shock chlorination, supplementary biocides, and the chromate inhibitor (zinc chromate phosphate). Isothiazolin was effective in depressing bacterial counts, but the other antibacterials tested (methylene bisthiocyanate, sulfone, and acrolein) permitted rapid regrowth of bacteria. Scaling was minimized by softening the water to reduce total hardness from 340 to 87 mg per liter as CaCO3. Suspended solids should be less than 10 mg per liter. Filtration and an alternate water supply must be available in case of wastewater treatment upsets. Non-chromate inhibitors (two polyphosphate-phosphonates and zinc polyolester) did not adequately protect the system against corrosion and loss of heat transfer. They allowed growth of sulfate-reducing bacteria. Use of the effluent in cooling towers will result in significant reductions of water use, water discharge, and contaminant discharge. (Cassar-FRC)

REFUSE OF POWER PLANT COOLING WATER FOR IRRIGATION,
California Univ., Riverside. Dept. of Soil and Environmental Sciences.
W. A. Jury, H. J. Vaux Jr., and L. H. Stolzy.
Water Resources Bulletin, Vol 16, No 5, 2 Fig, 10 Tab, 14 Ref.

Descriptors: *Powerplants, *Groundwater management, *Water reuse, *Cooling water, *Irrigation practices, California, Water policy, Saline water, Water quality management, Hydroelectric plants, Environmental protection, Evaporation, Impaired water use.

California water policy at present requires saline blowdown waters from powerplants to be disposed of in sealed evaporation ponds to prevent deterioration of groundwater. This policy attempts to strike a balance between demand for energy and environmental protection goals. Saline blowdown waters may be used in the irrigation of certain salt tolerant crops. When the irrigation is managed carefully, residual salts may be stored in the soil profile with litter potential for harming groundwater. Studies of blowdown irrigation water discharge below a successful irrigation project indicated a downward movement of salts below the root zone, but no farther than with conventional blowdown water disposal techniques. The reuse of blowdown waters for irrigation proved less costly than storage in evaporation ponds. These analyses showed that irrigation reuse of blowdown water is a viable means of saline water disposal within the existing standards of groundwater quality protection. (Geiger-FRC)

THE CHEMISTRY OF SALINE WATER CHLORINATION,
Tennessee Univ., Knoxville.
W. R. Haag.
PhD Thesis, June, 1981. 165 p, 24 Fig, 5 Tab, 119 Ref, 4 Append. University Microfilms International, Ann Arbor, MI; Order No GAX81-23155.

Descriptors: *Model studies, *Chlorination, *Saline water, *Chemical reactions, Industrial water, Cooling water, Powerplants, Environmental effects, Bromine.

A review of the present state of knowledge of natural water chlorination chemistry was performed, with particular reference to saline waters.

LIBRARY U. OF I. - URBANA CHAMPAIGN

Experimental work demonstrated that bromochloramines can readily form under conditions of power plant cooling water chlorination, if saline water is used. Further experimental work explained the results of previous workers by showing that chlorine losses at very high doses in seawater are simply the result of chlorate and bromate formation which is negligible at normal doses. The most important chlorine-produced oxidants, along with the relevant chemical reactions, were chosen as a basis for a kinetic model of saline water chlorination chemistry. Kinetic data were compiled in a computer program which simultaneously solves 24 differential equations, one for each species modelled. Estimates were made for the unknown rate constants, with the hope that measured values would be determined by future researchers. A purely predictive model was not possible due to the great variability in the organic demand; however, the model is applicable under a broad variety of conditions (except sunlight), and its provides a reasonably good description of a halamine chemistry under environmental conditions. 3D. Conservation In Domestic and Municipal Use

CONSERVING WATER THROUGH PRICING,
State Univ. of New York at Albany.
E. F. Renshaw.
Journal of the American Water Works Association, Vol 74, No 1, p 2-5, January, 1982. 4 Fig, 11 Ref.

Descriptors: *Water conservation, *Water shortage, *Pricing, Water demand, Water use, Economic aspects, Social aspects, Domestic water.

The success of water conservation efforts and availability of new technologies for reducing water consumption in households and industries suggest that conservation opportunities should be explored before projects to augment water supply are initiated. Classical economic theory illustrates the benefits of pricing water at the long-run marginal cost rather than the long-run average cost. The regressive nature of such a pricing policy could be combated by giving lump sum credits to deserving households or businesses, independent of actual water use. Lifeline rates and progressive rate structures have considerable appeal, but are neither an efficient way to ration water nor an equitable way to redistribute income. To maximize social benefits from water it is necessary to minimize social costs, which consist of cost to the utility of supplying water and the loss of consumer surplus that is likely to result from a water shortage. While nonprice rationing has achieved a high degree of social acceptance in communities that have experienced a water shortage, it will usually result in a larger economic loss than would be the case if wate were rationed by means of a higher price. A temporary system of penalty rates for excessive use and conservation credits would encourage more rational allocation of available water during shortages. Such systems appear to be acceptable by the public. (Carroll-FRC)

LEAK DETECTION--HISTORIES,
Alvord, Burdick and Howson, Chicago, IL.
J. E. Pilzer.
Journal of the American Water Works Association, Vol 73, No 11, p 565-567, November, 1981.

Descriptors: *Leakage, *Water distribution, Water conservation, *Water loss, *Water supply systems, Municipal water.

Several case histories of leak detection in water systems are reported from a survey of water companies and consultants by the American Water Works Association leak detection committee. In most cases discovery of leaks, some very large and some multiple small leaks, saved considerable water and money. A practical leak detection program can start with a modest overall study to determine where pinpoint leak detection would be most productive. Review of records can identify areas for closer scrutiny. The leak survey may be performed by water company personnel or an outside consultant. It is important to use the proper detection equipment, which filters some of the background noise that makes detection difficult. As energy and chemical costs escalate, leak detection should be considered even in systems with relatively low losses. (Cassar-FRC)

LEAK DETECTION PROGRAMS RECOVER REVENUES,
Community Consultants, Inc., Provo, UT.
S. E. Sowby.
Journal of the American Water Works Association, Vol 73, No 11, p 562-564, November, 1981. 2 Fig.

Descriptors: *Leakage, *Water metering, *Water distribution, Water conservation, *Operating costs, Water loss, Municipal water, Benefits, Case histories.

Seven case histories of leak detection in towns located in the semiarid western U.S. are given. In the first case, an average daily use of 1500 gal per person indicated that losses were occurring. Investigations showed that 33% of the raw water supply was leaking into a stream, and another 17% was being lost from the distribution system. In case 2, an old lead joint pipe had 21 leaks, which lost 50% of a town's water supply during a drought. In the third case, metering located a crushed pipeline leaking 4 mgd or 20% of a Utah city's supply into a river. Repair of 23 large meters in the fourth example increased an Idaho city's water revenue by $100,000 per year at a cost of $5000 in repairs. In a Colorado city, the fifth example, 55% of meters were broken or inaccurate, not accounting for 18-43% of the water metered into the system. In case 6, metering an entire city reduced waste by 30%, and leak detection located 32 leaks. In the last case, malfunctions and leaky valves were causing losses. (Cassar-FRC)

BENEFITS FROM WATER CONSERVATION DEPEND ON COMPREHENSIVE PLANNING,
Minnesota Univ., Minneapolis. Dept. of Civil Engineering.
W. J. Maier, J. DeZellar, and R. M. Miller.
Water Resources Bulletin, Vol 17 No 4, p 672-677, 1981. 2 Fig, 8 Tab, 12 Ref. OWRT B-139-MINN. 14-34-0001-8092.

Descriptors: *Water use, *Water conservation, Wastewater treatment, *Water treatment facilities, Water demand, Drought, Pollution load, Costs.

Experiences during the 1976-77 drought in California indicated that substantial savings in water consumption can be achieved under emergency conditions, resulting in some problems in wastewater treatment plants. In contrast, planned water conservation can be engineered to provide maximum monetary benefits when conservation programs coincide with increased populations to be saved. Fortunately, the self-cleaning hydraulic characteristics of circular channels, such as sewers, are relatively insensitive to flow over a wide range, reducing the problems caused by increased residence time. A computerized model study of effects of effluent flow reduction in a conventional municipal wastewater treatment plant indicated that the total BOD load discharged to receiving waters to reduced in direct proportion tothe flow reduction. The higher influent concentrations were compensated by increased residence time in the plant. The effects on suspended solids are similar. Treatment plant operating costs are relatively insensitive to hydraulic loading, resulting in an increase per unit volume of sewage treated. The net effect, however, is a decrease in per capita customer charges. (Baker-FRC)

REDUCING THE FLUSH,
Building Research Establishment, Watford (England).
C. J. D. Webster, and P. J. Davidson.
Water, No 42, p 12-16, 1981. 5 Fig, 3 Ref.

Descriptors: *Flushing, *Water conservation, Domestic water, Domestic wastes, *Toilets, Wastewater, Design criteria, Great Britain.

Efforts are underway to reduce the amount of water used in dwellings and elsewhere for domestic purposes. The flushing of water closets (WCs) is estimated to account for up to 20% of the total public water supply although complexities may be involved in obtaining optimum savings from this area. Current pans used in the United Kingdom are designed to operate on a 9 liter flush, as there has been little incentive until now to design for a lower volume. In the absence of immediately available WCs using reduced flush volumes, the use of dual flush systems is an immediate strategy which both follows the normal replacement approach and depends on the user's mode of operation for its saving. The dual flush principle has been available for a long time, giving the user the option of about 4-5 liters or the full 9 liters. All trials have reported substantial water savings. Controlled flush cisterns are arranged so that flushing terminates as soon as the handle is released. In dwellings where there is a metered water supply there is some financial incentive to the householders to install a new system. It is thought to be possible to design a suite that will perform acceptably at three liters or a little more, and that such suites can be used in most drainage installations, subject to certain restrictions. Changes in urinal structure are also discussed. (Baker-FRC)

THE TRADITIONAL APPROACH TO WATER LOSS,
Thames Water Authority (England).
J. S. Pocock.
Water, No 42, p 43-44, 1982.

Descriptors: *Water loss, *Water supply development, Water demand, Water management, *Pipelines, Leakage, *Water conservation, Design standards.

At intervals of about every 30 years an apparent interest in water losses has surfaced. The need for better materials and better standards of design was recognized at a very early stage. Detailed regulations regarding the customers' fittings and pipework were introduced in 1871. Recently the institution of consumer protection policies has done away with the threat of retribution wherein water supplies could be shut off in cases of uncontrolled water waste in London. One of the earliest means of assessing the effectiveness of a system of waste control was that of comparing the total consumption in different towns on a per capita basis. A remarkable correlation was found between the demand growth rates of four British towns, and it was concluded that at any time within that period an effective waste control policy would have had a significant impact on the capital program of the organization. The financial return derived from an increase of effort in waste control can vary widely from place to place in an authority's area, perhaps by a factor of as much as 20. (Baker-FRC)

A MULTIVARIATE ANALYSIS OF MUNICIPAL WATER USE IN UTAH,
Utah State Univ., Logan.
R. D. Hansen.
PhD Thesis, 1981. 102 p, 14 Fig, 18 Tab, 32 Ref, 4 Append. University Microfilms International, Ann Arbor, MI; Order No GAX81-20713.

Descriptors: *Water use, *Multivariate analysis, *Municipal water, *Model studies, Water supply, Drought, Groundwater, Surface water, *Utah.

This work formulates two multivariate models for the study of municipal water systems: (1) a monthly time series model for use in analyzing water use and (2) an additive logit model for analyzing water system response to drought. Both models are applied to Utah data. The time series regression model is used to study water demands in the Salt Lake City Water Department (SLCWD), Ogden City, and Granger-Hunter Improvement District service areas. The research shows that real price, as well as three weather/climate variables--average temperature, total precipitation, and daylight hours (percent)--has a significant impact on water usage in Utah. The usefulness of a monthly time series model for examining water management options is demonstrated. A hypothetical peak-season pricing scheme is examined. The characteristics of municipal systems which restricted water usage during the 1976-77 drought are studied using a logit model. This model specifies that the natural logarithm of the odds in favor of a municipal system having restrictions is a function of the size of the system, the percentage of individual connections served by separate outdoor systems, and the variability of the water supply. It is found that systems which rely heavily on surface water supplies were more vulnerable to drought conditions that those using groundwater or a combination of sources. The larger systems had a higher propensity for using restriction during the drought, as did those systems without separate pressure irrigation. (Sinha-OEIS)

3E. Conservation In Industry

STATUS AND PROBLEMS OF PROCESS WATER SUPPLY IN THE FRUIT AND VEGETABLE PROCESSING INDUSTRY (SITUATION UND AUFGABEN DER BETRIEBSWASSERWIRTSCHAFT IN DER OBST- UND GEMUSEVERARBEITENDEN INDUSTRIE),
M. Henkel, and M. Richter.
Wasserwirtschaft-Wassertechnik, Vol 31, No 10, p 358-359, 1981. 3 Fig, 2 Tab. (No English summary).

Descriptors: *Industrial water, *Food processing industry, *Water management, Water reuse, Fruit crops, Vegetable crops, Process water, Water conservation, Effluents, Wastewater discharge, Economic aspects, Social aspects, Water use.

A survey of 56 representative fruit and vegetable processing plants in the German Democratic Republic revealed that the status of water management in these industries is generally unsatisfactory. Considerable differences in quantities of water consumed per unit finished product were found even within the individual branches (product groups) of fruit juice, canned products, frozen products, fresh products, jams and jellies, and baby foods. Water supply becomes especially problematic for these firms when dry periods coincide with the start of the busy season. Only about half of the plants queried had information on their wastewater discharges, and most of these determined only degradable/filterable substances and pH. Of the approximately 50% of the plants surveyed which discharged their wastewaters directly into receiving streams, only 46% had even mechanical treatment plants, and 39% had to pay discharge fees. The responsibility of plant managers for water management is clearly outlined in East German law. Suggestions for improving the currently unsatisfactory situation included metering, increasing the consciousness of employees regarding water conservation, inclusion of water specialists in plant planning, and increasing research programs for specific industries. A few instances of successful water conservation projects are listed, including addition of condensate from fruit juice concentration to the transport water, recycling water from autoclaves and pasteurizers, recycling raw fruit wash water, and other in-plant reuse. (Carroll-FRC)

3F. Conservation In Agriculture

A CONCEPTUAL FRAMEWORK FOR EVALUATING AGRICULTURAL WATER CONSERVATION POTENTIALS,
California Univ. Davis. Dept. of Land, Air, and Water Resources.
D. C. Davenport, and R. M. Hagan.
Water Resources Bulletin, Vol 16, No 4, p 717-723, August, 1980. 3 Fig, 2 Tab, 17 Ref.

Descriptors: *Water losses, *Agricultural, *Evapotranspiration, *Water conservation, Methodology, Irrigation efficiency, Runoff, Subsurface runoff, Evaporation, Water reuse, Water quality, Water management, Water use efficiency, Seepage control.

Types of water losses in agriculture are defined and potential conservation measures outlined. Recoverable water remains on or below the land surface and includes seepage, leakage, spills, surface runoff and percolation below the root zone. Water is irrecoverably lost by evaporation from soil or water bodies and by transpiration from plants. The largest potential for water conservation is in reducing irrecoverable losses. Possible methods include reducing the ratio of open water surface to total volume in ponds and reservoirs, using groundwater storage via recharge ponds, applying evaporation supressants to surfaces of water bodies, irrigating at night, using drip irrigation and mulches, growing shorter season crops or varieties, reducing the cropped area and the acreage of phreatophytes, using deficit irrigation, withholding water at nonsensitive growth stages, applying foliar antitranspirants, adjusting planting dates to avoid high evapotranspiration periods, changing row direction and plant spacing to alter solar and advected energy, and controlling weeds. Recoverable water losses may be managed by recovery and reuse of water, reducing further losses, and intercepting water before it reaches the sea and becomes unusable. Advantages and disadvantages of reducing recoverable and irrecoverable losses by these methods are discussed. (Cassar-FRC)

IRRIGATION PRACTICES FOR RECLAIMED ALKALI SOILS,
Central Soil Salinity Research Inst., Karnal (India). Div. of Engineering.
V. V. D. Narayana, and N. K. Tyagi.
Journal of the Irrigation and Drainage Division, Proceedings of the American Society of Civil Engineers, Vol 107, No IR4, p 400-406, December, 1981. 4 Fig, 2 Tab, 8 Ref.

Descriptors: *Irrigation efficiency, *Border irrigation, *Crop production, *Alkaline soils, Irrigation practices, Contour irrigation, Crop yield, Rice, Wheat, Mathematical studies, Slopes, Grading, *India.

Field experiments were carried out in India to compare irrigation efficiency on graded and level borders, determine the stream cutoff point, and determine the optimum border dimensions and see how sloping borders could be adopted for rice or wheat cultivation on alkali soils. With the prevailing gentle land slope of 0.1-0.2% as the border grade, wheat and rice can be grown in a layout of graded and closed borders in rotation. Light and frequent irrigations may be applied by cutting off irrigation once it has advanced to 70% of the border length. Irrigation efficiencies in small fields which are common in the Indo-Gangetic alluvial plains may be enhanced by using graded borders with lengths ranging from 50 to 70 m and widths from 6 to 8 m. These graded borders may also be used for growing rice during the rainy season by dividing them into two or three compartments connected by asbestos pipes. The rice yield estimates for a sloping border layout in two or three compartments are 65.4 and 67.7 quintals/ha, respectively. (Geiger-FRC)

DIMENSIONLESS STREAM ADVANCE IN SLOPING BORDERS,
Science and Education Administration, Phoenix, AZ. Conservation Lab.
T. Strelkoff, and A. J. Clemmens.
Journal of the Irrigation and Drainage Division, Proceedings of the American Society of Civil Engineers, Vol 107, No IR4, p 361-382, December, 1981. 18 Fig, 6 Ref.

Descriptors: *Mathematical studies, *Infiltration, *Mathematical models, *Border irrigation, Irrigation, Stream banks, Graphical methods, Streambeds, Rrunoff, Model studies, Recession curve.

A simple case of general stream border advance contains a plane border of great length and a constant inflowing discharge prior to cutoff. The advance curve is controlled by border slope, roughness, infiltration, and inflow discharge and cutoff time. If the advanced function is viewed in dimensionless terms, the number of controlling parameters is significantly reduced. If only advance prior to inflow cutoff is of interest, then two dimensionless parameters govern the dimensionless advance curves. Methods of applying kinematic-wave theory to the computation of border-irrigation flow proved simpler than the zero-inertia analysis employed for the general case. Using a dimensionless boundary value as a pertinent controlling variable increased the number of dimensionless governing parameters to three. Difficulty in representing a three-parameter family of advance curves was overcome by using normal depth as the characteristic depth and equating the dimensionless parameter for bed slope to one. Curves were given representing all practical cases of advance of an irrigation stream over a plane border with inflow that is constant prior to cutoff. (Geiger-FRC)

SUBSURFACE TRICKLE IRRIGATION MANGEMENT WITH MULTIPLE CROPPING,
Department of Agriculture, Phoenix, Arizona, Water Conservation Laboratory.
D. A. Bucks, L. J. Erie, O. F. French, F. S. Nakayama, and W. D. Pew.
Transactions of the ASAE, Vol 24, No 6, p 1482-1489, November/December, 1981. 6 Fig, 5 Tab, 17 Ref.

Descriptors: *Irrigation efficiency, *Crop yield, *Evapotranspiration, *Trickle irrigation, Subsurface irrigation, Surface irrigation, Cultivation, Cantaloupes, Onions, Carrots, Productivity, Planting management, Soil-water-plant relationships.

Subsurface trickle irrigation with multiple cropping and minimum cultivation had many advantages over surface trickle irrigation: minimal interference with field operations, continuous production of two or more row crops without replacement of trickle lines, and extension of the useful life of a trickle system over a larger production base. Spring and Fall cantaloupes were grown on a clay loam soil with moderately saline water in 1977, 1978; dry onion and carrots in spring 1979; and fall cantaloupe in 1979. Cantaloupe yield was higher with weekly than with daily trickle irrigation; onion yield was higher with daily irrigation. Carrot yields were not affected by irrigation frequency. Production was highest at water application rates equal to or slightly higher than the seasonal evapotranspiration values for furrow irrigation. Maximum cantaloupe production was obtained with an average evapotranspiration of 51 cm for the spring crop and 39 for the fall crop. Seasonal evapotranspiration values for trickle irrigated onions and carrots were 56 cm and 41 cm, respectively. Roots of these plants did not clog the subsurface irrigation lines. (Cassar-FRC)

ENERGY, WATER, AND COST TRADE-OFFS IN IRRIGATION SYSTEM SELECTION AND MANAGEMENT,
California Univ., Davis.
R. M. Hagan, and E. B. Roberts.
Transactions of the ASAE, Vol 24, No 6, p 1539-1545, November/December, 1981. 1 Fig, 6 Tab, 14 Ref.

Descriptors: *Energy, *Cost analysis, *Irrigation efficiency, Water requirements, Irrigation design, Management, Surface irrigation, Sprinkler irrigation, Furrow irrigation, Electric power, Pumping, Peak demand, Water costs.

Energy, water, and cost tradeoffs were examined in detail for 28 variations of irrigation system design and operation. These included sprinkler irrigation (hand-move, wheel-line, four types of center-pivot, and two types of lateral-move) and furrow irrigation (four types of graded and two types of level). The assumed crop was cotton growing in the San Joaquin Valley on very fine sandy loam soil. Both inexpensive, low energy water and expensive, high energy water were considered. Changes made to conserve water either increased or decreased annual energy requirements and annual costs. No single system provided the lowest energy requirements, water requirements, and costs. A guide is given to determine the feasibility of shifting irrigation pumping away from peak electrical use hours. It considers the water supply capacity, irrigation system capacity, and other factors such as labor and capital costs. Suggestions are given for modifying systems if changes are feasible. Descriptors: *Water use efficiency, Soybeans, *Irrigation efficiency, *Crop production, *Soil-water-plant relationships, *Cost-benefit analysis, Corn, Sorghum, *Great Plains.

Rapidly increasing demands on usable water resources, and escalating energy costs, with virtually stable or falling farm commodity prices have resulted in production pressures and cost-price squeeze situations for agriculture, particularly irrigated agriculture, in the corn-soybean-sorghum areas of the Great Plains. Actual out-of-pocket pmping costs have doubled or tripled in 4-6 years in most areas, and are projected to double again in the next 8-10 years. These circumstances are especially important to the irrigator with high lifts or in an area of especially high energy costs. The situation described makes it essential that the irrigator know, for each crop, the time of most critical water need by that crop, the amount to supply, and the nature of the water supply-yield response curve, so that he can manage his water supply to the best advantage. If two or more crops need water simultaneously and his water supply or funds available are limited, he needs to make a decision as to which crop to water and suffer the least economic loss. For more than three decades, information has been available on the consumptive use: total, seasonal distribution of need and critical periods of need of water by corn. The results of most investigations in the northern Great Plains point to a peak period of maximum daily use corresponding with the grand period of growth through tasseling-silking. Some studies agree on the critical nature of the tassel-silk brown stage for maximum yield impact. Because of the above quite well established information for corn, it was felt that a more productive study area would be the water regimes most profitable and productive for soybeans.

WATER MOVEMENT FACTORS IMPORTANT TO THE DESIGN AND OPERATION OF SUBIRRIGATION SYSTEMS,
North Carolina State Univ. at Raleigh. Dept. of Biological and Agricultural Engineering.
R. W. Skaggs.
Transactions of the ASAE, Vol 24, No 6, p 1553-1561, November/December, 1981. 11 Fig, 1 Tab, 23 Ref.

Descriptors: *Irrigation design, *Drain spacing, *Subsurface irrigation, *Soil water movement, Design criteria, *Drainage systems, Soil properties, Water table fluctuations, Model studies.

Design of subirrigation and drainage systems depends on soil properties, crop, and climate. Movement in these systems is lateral from a drain or open ditch (saturated flow) and vertical in the zone above the water table (unsaturated flow). Three operational modes are considered in design of a subirrigation system. (1) Steady state--the drains should be spaced to maintain the desired water table depth range during long periods of high evapotranspiration. (2) Transient state--the system should be designed to manipulate the water table as desired in case of operator error, equipment failure, or low levels at the beginning of the growing season. (3) Subirrigation under changing weather conditions--the operation of the system in both deficient and excessive rainfall periods should be considered. Methods are given for calculating the position and shape of the water table during steady state and transient subirrigation. Use of the water management model, DRAINMOD, for operation of a subirrigation system under changing weather conditions is discussed. A drainage system is developed for a 110 acre field of sandy loam underlain by sandy clay loam near Farmville, North Carolina. Optimum drainage spacing is 18 m for subirrigation-drainage and 25 m for conventional drainage alone. (Cassar-FRC)

WATER USE EFFICIENCY AND ROTATIONAL WATER SUPPLY AT THE FARM LEVEL: CERTAIN RESULTS FROM AN EXPERIMENTAL PILOT PROJECT IN GUJARAT STATE, INDIA,
Mahi-Kadana Irrigation Project, Ahmedabad (India).
T. K. Jayaraman.
Water Supply and Management, Vol 5, No 6, p 391-399, 1981. 1 Fig, 5 Tab, 7 Ref.

Descriptors: *Irrigation efficiency, *Water use efficiency, Rotational irrigation, Irrigation practices, *India, Agriculture, Water management, Social aspects, Economic aspects, Vegetable crops.

Pilot studies (1976-1980) in the 557 ha Mahi-Kadana project, India, showed that rotational irrigation in the rabi season increased water use efficiency to 69% the season the method was introduced and 72% after the system was stabilized. Water use efficiency in the 2 years before rotational irrigation were 41% and 59%. The total number of rrigated acres increased 9% after rotational irrigation. Cropping intensity also increased from 57-78% during the control years to 85% under rotational irrigation. The total water drawn from November to March averaged 532.70 and 569.76 cusecs in the control years and 530.76 and 509.19 cusecs in the rotational irrigation years. A survey of farmers after the project was completed showed that owners of both large- and small-size holdings supported the program. Quarreling over water supplies and worry about receiving water on time had been eliminated. (Cassar-FRC)

ENERGY AND WATER CONSERVATION STRATEGIES IN IRRIGATED AGRICULTURE,
California Univ., Berkeley. Lawrence Berkeley Lab.
R. L. Ritschard, and K. Tsao.
Water Resources Bulletin, Bulletin, Vol 16, No 2, p 340-347, April, 1980. 1 Fig, 2 Tab, 15 Ref.

Descriptors: *Water conservation, *Drought, *California, *Irrigation practices, Irrigation, Farming, Water supply, Water management, Energy, Energy conservation.

Conservation strategies applicable to California are considered in the light of the drought of 1976 and 1977. These strategies include increased use of ground water, increased irrigation efficiencies, and shifts in cropping patterns. These modifications lessened the losses due to the drought. However, some of these changes may have caused problems for future water supply, for example the extensive pumping of ground water supplies and ground subsidence. Changes in irrigation practices may have affected the salt balance for future years. Maintaining and augmenting surface water supply, increasing power use efficiencies, and improving irrigation efficiencies are viewed as potential conservation strategies for that region. Electricity savings associated with water conservation have been estimated to be as much as 25%. Specific near term actions suggested for facilitating conservation include an expanded irrigation management system, efficient water deliveries, and a continued effort on the part of individual growers to use resources during periods of normal rainfall as they were used under drought conditions. SIMPLE EQUATIONS FOR HOOGHOUDT EQUIVALENT DEPTH,
Democritos Univ. of Thraki, Xanthi (Greece). School of Engineering.
J. G. Sakkas, and V. Z. Antonopoulos.
Journal of the Irrigation and Drainage Division, Proceedings of the American Society of Civil Engineers, Vol 107, No IR4, p 411-414, December, 1981. 1 Tab, 4 Ref.

Descriptors: *Hydrologic models, *Design criteria, *Tile drainage, *Mathematical equations, Mathematical studies, Drainage, Drain spacing, Drainage practices, Drainage engineering, Drains, Mathematical models.

The Hooghoudt equation for drainage design problems has been reworked and simplified by other researchers to include dimensionless variables. Unique nomographic solutions for the equivalent depth and drain spacing formulas may be used in conjunction with elaborate computer prorams to solve transient flow problems. For faster estima-

tions of the equivalent depth which avoid storage of a table in the computer memory, approximate fomulas have been developed which may be reworked into simple algebraic expressions. A series of values for the drain spacing function was used to fit three curves to the data by the least squares method. The relative error using these solutions was dependent upon the radius of the tile drains. The simplified formulas show no appreciable loss of accuracy and may be used to compute the equivalent depth for steady or unsteady state drainage problems with a desk calculator or digital computer. WILL NEW ORLEANS MISS THE MISSISSIPPI,
Louisiana State Univ., Baton Rouge. Dept. of Civil Engineering.
R. G. Kazmann.
Journal of the American Water Works Association, Vol 73, No 11, p 18, 20, November, 1981. 1 Fig.

Descriptors: *Saline water intrusion, *Disasters, *Water supply development, *New Orleans, Louisiana, *Mississippi River, *Atchafalaya River, Municipal water, Rivers, Flood damage, Flood control, Old River Control Complex, Conjunctive use, Water resources development, Water management, Injection wells, Alternative planning, Potential water supply, Water control.

Cities with water supplies vulnerable to natural disasters should plan alternate means of obtaining water. New Orleans faces the possibility of losing Mississippi River flow to an alternate distributary, the Atchafalaya River. Throughout the early 20th century an increasing proportion of river flow entered the Atchafalaya, reaching greater than 30% by 1954. The Old River Control Complex was built at the point where the Atchafalaya and the main stem are closest, near Simmesport. This structure consists of a spillway and an overland structure to assist during floods. The Atchafalaya channel continued to deepen and build a higher flood plain in the lower basin. The 1973 flood greatly weakened the control structure. If this is destroyed by a future flood, 70% of the river flow would be diverted through the Atchafalaya. Although navigation in the New Orleans area would not be affected, the Mississippi River water could become saline, unusable for drinking or industrial purposes. A proposed scheme to provide water to the city under these circumstances is conjunctive use of groundwater and water from the Pearl River. A treatment plant would inject filtered surplus river water into a well field, prventing land subsidence from excess groundwater withdrawals. Although the Corps of Engineers claims that the Mississippi River can be kept in its present course indefinitely, the author suggests that an alternate supply must be established for New Orleans before a catastrophe occurs. DETENTION BASINS--AN URBAN EXPERIENCE,
Georgia Inst. of Tech., Atlanta.
T. N. Debo, and H. Ruby.
Public Works, Vol 113, No 1, p 42-43, 93-94, January, 1982.

Descriptors: *Flood control, *Detention reservoirs, *Urban drainage, Maintenance, Safety, Retention basins, Basins, *Atlanta, Georgia, Runoff, Evaluation.

Detention basins, encouraged for runoff control in the Atlanta, Georgia, metropolitan area, also produce problems. These include maintenance problems and health and safety problems. Detention basins do not effectively control flooding in all situations. Sometimes all the drainage is concentrated in one drainage channel. The combined effects of several detention basins may change the timing of flood discharges so that higher peak flows will occur than would have occurred under natural conditions. The many swimming pool-sized detention basins have little effect on downstream flooding. Erosion may also be increased. Detention basins designed for a 100-year flood have little flood control effect on a 5- or 10-year storm. Costs assessments of detention basins should consider loss of valuable land for building, esthetics, and loss of tax revenue. A survey of residents living near 15 small detention basins showed that 68% said no water accumulated in the basins, 12% felt the basins decreased flooding problems, and 5% felt drainage problems were aggravated. Over 70% did not realize that adjacent property owners were responsible for maintenance. A survey of engineers indicated that many basins were not functioning as planned and that only basins in developments of 20 acres or more had a major positive flood control effect. (Cassar-FRC)

Descriptors: *Reservoirs, *Water storage, *Planning, Design criteria, Management planning, *Reservoir operation, Flow control, Reservoir releases, Water demand.

Storage reservoirs, as important components of water management systems, must be carefully designed and operated. The general flow equalization goal of storage reservoirs, either in terms of constant release throughout the year or of demand-based release, must be achieved with the smallest possible storage volume. The most important factors influencing the selection of storage volume are the distribution function of the inflow (coefficient of variation and skewness), the determination interval, the long-term and short-term persistence characteristics of the inflow series, the demand or release function, the operation or balancing time, the initial level of the reservoir, and the simulation model of the experimental method. The simple autoregression model or Markov model is generally superior to the fractional noise model. For annual determination intervals, series of at least 1000 data runs are required in order to assure 99% reliability of coverage of the demand with the selected storage volume. Optimal reservoir operating plans, in terms of maximal compensation of the flow variations, were developed using the 'rule of clamped thread', i.e., a process for calculating the shortest path through a corridor of irregular shape. the inherent unpredictability of future inflows emphasizes the great significance of large data series, especially in the case of smaller reservoirs. MONEY DOWN THE DRAIN,
Hydraulics Research Station, Wallingford (England).
P. Colyer.
Water, No 42, p 6-9, 1982. 2 Fig.

Descriptors: *Urban drainage, *Economic aspects, Computers, Automation, *Design criteria, Management, Construction, Water management, Drainage, Storm drains, *Urban runoff.

Due to the great expense involved in urban drainage networks, it is imperative that the system be efficient, well founded and accurate regarding design, construction and management. The Wallingford Procedure is a set of computer programs and accompanying reports which embody the latest recommendations on urban storm drainage. It is based on research started in 1974 at the Hydraulics Research Station, the Institute of Hydrology and the Meteorological Office. The Procedure presented four alternative methods. One is appropriate for design work only, one for analysis only and two for both design and analysis. The Modified Rational method is based on the long-established principles of the Rational method, calculating peak runoff discharge only. The Optimising method determines flows from the Modified Rational method but a minimum cost design is produced. The Hydrograph method includes the full modelling procedure for surface runoff and free surface pipe or channel flow. The simulation method includes all the main features of the Hydrograph method and also extends to surcharge analysis and surface flooding. Flapped outfalls can also be represented. The computer package is available from the Hydraulics Research Station. (Baker-FRC)

4B. Groundwater Management

SOIL PERCOLATION RATES FROM NEUTRON PROBE MEASUREMENTS,
Oregon State Univ., Corvallis.
T. S. Vinson, and L. Mahar.
Journal of the Irrigation and Drainage Division, Proceedings of the American Society of Civil Engineers, Vol 107, No IR4, p 343-359, December, 1981. 14 Fig, 3 Tab, 31 Ref.

Descriptors: *Groundwater movement, *Groundwater management, *Moisture probe, Spray irrigation, Percolation, Moisture meters, Moisture profiles, Soil columns, Moisture content, Irrigation water.

Studies were conducted to assess the feasibility of using subsurface neutron moisture probes to estimate soil percolation rates as part of a long-term research project to determine hydrologic conditions at a spray irrigation facility. The new technique utilizes the soil moisture content in relation

LIBRARY U. OF I.- URBANA CHAMPAIGN

to time obtained at two levels in a soil column or profile in which one-dimensional percolation is taking place. The procedure was validated in laboratory percolation tests using 10 columns filled with well graded sand. The calculated quantities of water during these trials agreed well with the actual amounts of water collected from each column. The procedure is simpler than traditional percolation rate tests, but its validity for layered soil profiles or shallow groundwater table conditions has yet to be ascertained. When performing in situ measurements using the neutron moisture probes, consideration should be given to the method of installation of the access tube, the time intervals at which moisture contents will be recorded at each site, the distance between levels where moisture content values are taken, and the depth from the ground surface to the level where moisture content readings are recorded. THE RESPONSE OF GROUNDWATER TO ARTIFICIAL RECHARGE SCHEMES,
Thessaloniki Univ., Salonika (Greece). School of Technology.
P. Latinopoulos.
Water Resources Research, Vol 17, No 6, p 1712-1714, December, 1981. 3 Fig, 3 Ref.

Descriptors: *Groundwater recharge, *Artificial recharge, *Aquifers, Mathematical studies, Groundwater movement, Recharge, *Groundwater management, Unconfined aquifers, Groundwater storage, Transmissivity, Seasonal variation.

Analytical solutions for the groundwater flow in an unconfined aquifer showed that uniform recharge rates over the whole period of recharge are not the optimal solution. A greater net gain (up to 24%) in aquifer storage and outflow can be obtained by distributing the recharge volume over several periods of variable duration. Artificial recharge can be scheduled, knowing the effects of seasonal variations in infiltration. (Cassar-FRC)

A LUMPED APPROACH TO THE INVERSE PROBLEM IN GROUND WATER HYDROLOGY,
Youngstown State Univ., OH. Dept. of Civil Engineering.
I. A. Khan.
Water Resources Bulletin, Vol 16, No 5, p 866-873, October, 1980. 5 Fig, 23 Ref.

Descriptors: *Groundwater, *Geohydrology, Groundwater hydrology, *Model studies, *Groundwater movement, Computers, Hydrologic models, Simulation, Water resources development, Water supply development.

A solution for the inverse problem in groundwater has been proposed, based on the lumped approach. For the purpose of illustrating the solution procedure, a hypothetical aquifer having impermeable boundaries was considered. Of primary concern was the demonstration of the validity of the approach and the observance of the convergence characteristics of the search algorithm. The aquifer is unconfined, having uniform depth of 100 ft, overlying a horizontal impermeable bed. It is 8000 feet wide and 12,000 feet long and has five pumping wells of various capacities. The inverse model uses a simulation model and approximate boundary conditions to generate values for surrogate permeabilities such that the model output agrees reasonably with the observed data. The emphasis is on the determination not of the conventional aquifer permeability, but of a surrogate permeability, so that the model can eventually be used for the management studies. The surrogate permeability should not be interpreted as a property of the porous media. It is simply a transformation constant in the management model. The advantage of such an approach is that the system complexities that are hard to determine essentially become incorporated into the surrogate parameters. The proposed method also allows the same ground water flow equations and the same solution procedure with the same initial and boundary conditions to be employed both in the identification process and in the subsequent management studies. This tends to minimize errors inherent in a simulation process. (Baker-FRC)

Descriptors: *Borehole geophysics, *Groundwater, *Water management, *Data collections, Aquifers, Observation wells, Monitoring, Geohydrology, Carbonate rates, Water quality, Water level, *Florida, *Floridan aquifer.

Management of ground-water resources within the Southwest Florida Water Management District requires that hydrogeologic characteristics of water-bearing rocks and quality characteristics of water be described. Wells for the District's Regional Observation and Monitor Well Program are drilled specifically to collect data to describe the groundwater resource. Suggested borehole data-collection methods for these wells include drilling in stages; running geophysical logs at the completion of each stage; collection of water-level and specific-conductance data before, during, and after a day's drilling; specific-capacity determinations after a day's drilling; and placing a packer in the gypsiferous and anhydritic limestone and dolomite for water-level and water-quality data. EFFECT OF IRRIGATION PUMPING ON THE GROUND-WATER SYSTEM IN NEWTON AND JASPER COUNTIES, INDIANA,
Geological Survey, Indianapolis, IN. Water Resources Div.
M. P. Bergeron.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-137688, Price codes: A05 in paper copy, A01 in microfiche. Geological Survey Water-Resources Investigations 81-38, August, 1981. 73 p, 33 Fig, 7 Tab, 25 Ref.

Descriptors: *Groundwater, *Irrigation, *Pumping, *Surface-groundwater relations, Groundwater movement, Model studies, Simulation analysis, Aquifers, Aquifer characteristics, Bedrock, Water level fluctuation, Drawdown, Glacial drift, *Groundwater mining, Groundwater recharge, *Indiana, Newton County, Jasper County, Hydraulic conductivity.

Flow in the ground-water system in Newton and Jasper Counties, Indiana, was simulated in a quasi-three-dimensional model in a study of irrigation use of ground water in the two counties. The ground-water system consists of three aquifers: (1) a surficial coarse sand aquifer known as the Kankakee aquifer, (2) a limestone and dolomite bedrock aquifer, and (3) a sand and gravel bedrock valley aquifer. Irrigation pumping, derived primarily from the bedrock, was estimated to be 34.8 million gallons per day during peak irrigation in 1977. Acreage irrigated with ground water is estimated to be 6,200 acres. A series of model experiments was used to estimate the effects of irrigation pumping on ground-water levels and streamflow. Model analysis indicates that a major factor controlling drawdown due to pumping in the bedrock aquifer are the variations in thickness and in vertical hydraulic conductivity in a semiconfining unit overlying the bedrock. Streamflow was not significantly reduced by hypothetical withdrawals of 12.6 million gallons per day from the bedrock aquifer and 10.3 million gallons per day in the Kankakee aquifer. Simulation of water-level recovery after irrigation pumping indicated that a 5-year period of alternating between increasing pumping and recovery will not cause serious problems of residual drawdown or ground-water mining. This report describes sources, locations, quantity, and quality of ground water in a 350-square-mile area whose potential for irrigation development is being evaluated by the U.S. Bureau of Reclamation. The entire area is underlain by Precambrian Sioux Quartzite, which throughout most of the area is overlain by undifferentiated Paleozoic rocks. The Sioux and, where present, Paleozoic rocks are overlain unconformably by Cretaceous formations, including the Dakota and Niobrara Formations. Surface strata are Pleistocene and Holocene deposits of sand and gravel and Pleistocene glacial till. The Dakota and Niobrara Formations are each capable of yielding water sufficient for irrigation wells in parts of the area. Pleistocene and Holocene deposits yield adequate water for irrigation in the southern part of the area and along the flood plain of the Missouri River. Water from the Dakota Formation is so saline as to necessitate burdensome salinity-control measures for successful long-term irrigation use. That from the Niobrara Formation is suitable for irrigation of most crops. Water from Pleistocene and Holocene deposits is highly variable, but is suitable for irrigation in the southern part of the area and along the Missouri River. (USGS)

Water supply is a major government objective in the State of Baden-Wurttemburg, since available

groundwater reserves are concentrated in limited areas, while the remainder of the territory has inadequate local supplies. A major international highway, Autobahn A81, is under construction in this State. The vulnerability of the groundwater in the karstic formations is intensified by highway construction and anticipated petroleum pollution. In highway planning, important water-bearing formations were circumvented insofar as possible, but collecting regions are traversed over a distance of 24 km. Water protection plans were developed cooperatively by highway engineers, water supply planners and geologists. Where the clay marl layer generally overlying the karst was lacking, a special impermeable layer was applied in preparation of the roadbed. Piping was installed to divert highway runoff to suitable infiltration areas with oil protection. Fissures and cavities exposed during construction were also sealed with impermeable materials such as clay or cement. Protection costs were estimated at 9.6 million German Marks. Water supply security was simultaneously improved by installing additional filtration and biological equipment in affected water supply plants. Where the protection offered by these measures was judged inadequate, provisions were made for permanent or emergency water important. (Carroll-FRC)

The history and nature of irrigation institutions in the U.S. are described. Mathematical models of irrigation supplies assume that comprehensive irrigation management exists. In reality, the three major types of irrigation agencies (public irrigation disricts, mutual water companies, and commerical water companies) have limited power. With few exceptions, they have no direct control over groundwater depletion. Public irrigation districts are most powerful, followed by mutual companies, then by commerical water companies (which have virtually disappeared). Conjunctive use modelers should rely only on those decision variables controlled by the particular agency under study. (Cassar-FRC)

GROUNDWATER CONTROL,
King's Coll., London (England). Dept. of Civil Engineering.
J. K. White.
Civil Engineering (London), p 27, 29-31, December, 1981. 10 Fig.

Descriptors: *Construction methods, *Groundwater management, Unconfined aquifers, Confined aquifers, Dewatering, Groundwater level, *Excavation, Urbanization, Industrial development, *Coastal areas, Estuaries, *Water table.

Urban and industrial development occurring near rivers, coastal areas and estuaries where the water table is closest to the ground surface frequently calls for control of groundwater to be undertaken. Two types of control are considered. The first occurs when a foundation excavation goes below the water table in a saturated permeable material, such as gravel or sand, which lies above a substantial impermeable base. The second type of situation occurs when the excavation is in a relatively dry impermeable strata, which is near the surface but which overlies a saturated permeable material in which the water pressure would cause the water level in a stand pipe located in it to rise above the formation level of the foundation. Under these circumstances there is the risk that removal of the excavating material will cause sufficient imbalance between overburden and water pressure for the water to break through and flood the excavation. The method of control adopted will vary and depends on the circumstances. While experience plays a large and essential part in the specification of a dewatering system, there has been a growing demand in recent years for analytical justification for design. Models have been devised which are used to give more reliable estimates of well point performance when used in conjunction with sheet pile cut-offs in those cases where both the system and the cut-off partially penetrate an unconfined aquifer. (Baker-FRC)

4C. Effects On Water Of Man's Non-Water Activities

EVALUATION OF METHODS FOR DETERMINING URBAN RUNOFF CURVE NUMBERS,
Science and Education Administration, Beltsville, MD.
W. J. Rawls, A. Shalaby, and R. H. McCuen.
Transactions of the ASAE, Vol 24, No 6, p 1562-1566, November/December, 1981. 3 Fig, 5 Tab, 11 Ref.

Descriptors: *Urban runoff, *Hydrologic models, *Land use, Urban hydrology, Soil types, Rainfall-runoff relationships, Antecedent moisture, Soil water, Runoff curve number.

The runoff curve number, an important input parameter to the Soil Conservation Service's hydrologic models, integrates land cover, soil type, and antecedent soil moisture conditions. Data from 175 urban watersheds were used to determine runoff curve number by three methods: the contingency table approach (measuring the fractions of land use and soils separately and integrating them with a weighted average scheme), use of the U.S. Geological Survey land use maps, and the conventional approach (use of the overlay method with low altitude aerial photos, land use maps, and onsite investigations). Results indicated that estimates of runoff curve numbers were sensitive to the land use classification system and relatively insensitive to the method of integrating soils and land cover data. The detailed, time-consuming conventional approach was not necessary for watersheds of greater than 26 sq km. A set of runoff curve numbers was calculated for the three hydrologic soil groups for Level II U.S. Geological Survey land use categories. Although these were not in total agreement with those estimated by the conventional approach, the level of imprecision was considered satisfactory for most hydrologic studies. (Cassar-FRC)

CONSTITUENTS OF HIGHWAY RUNOFF; VOLUME I, STATE-OF-THE-ART REPORT,
Envirex Inc., Milwaukee, WI.
M. K. Gupta, R. W. Agnew, and N. P. Kobriger.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-241895, Price codes: A06 in paper copy, A01 in microfiche. Federal Highway Administration Report No FHWA/RD-81/042, February, 1981. 121 p, 16 Fig, 37 Tab, 169 Ref. DOT-FH-11-8600.

Descriptors: *Highways, *Roads, *Water pollution sources, *Storm runoff, *Urban runoff, Drainage effects, Particulate matter, Deicers, *Highway effects, Environmental effects, Heavy metals, Pesticides, Oxygen demand, Salt.

The factors which most affect quantity and quality of highway runoff are traffic volume, rainfall intensity and pattern, highway drainage characteristics, operation and maintenance characteristics and degree of imperviousness of the drainage area. Maintenance of adequate drainage is one of the most important aspects of highway design. Highway runoff characteristics are similar to those of urban runoff and may exert significant shock pollutional loads on receiving waters. The weighted average of total solids accumulations between successive street cleanings, a period of 2 to 12 days, for eight cities was found to be 1400 lb/curb mile. A high percentage of street surface pollutants are associated with very fine dust and dirt particles. Substantial quantities of toxic materials, such as heavy metals and pesticides, are present in street surface contaminants with the amounts varying considerably from site to site. Because of the consistent presence of heavy metals in amounts large enough to interfere with BOD5 measurements, COD is considered to be a better parameter for measuring the oxygen demand potential of highway runoff. Highway salting rates usually range from 400 to 1200 lbs per two-lane mile. Over the winter season, a typical multiple lane highway may use 100 tons or more of salt per mile. Significant amounts of vehicle released airborne matter are settled out and washed off the road surface during rainstorms. (Moore-SRC)

PRESCRIBED FIRE: EFFECTS ON WATER QUALITY AND FOREST NUTRIENT CYCLE,
Duke Univ., Durham, NC. School of Forestry and Environmental Studies.
D. D. Richter, C. W. Ralston, and W. R. Harms.
Science, Vol 215, No 4533, p 661-663, February 5, 1982. 1 Fig, 1 Tab, 8 Ref.

Descriptors: *Forest management, *Water quality, Cycling nutrients, Phosphorus, Sodium, Nitrogen, Carbon, Calcium, Magnesium, Water pollution sources, Groundwater, Forest soils, Hydrology, Nutrients, *Forest fires, Environmental effects, Runoff.

This report examines both off-site and on-site effects of a series of prescribed fires on experimental watersheds in the Lower Coastal Plain of South Carolina. Studies of off-site effects were concerned with fire-caused exports of materials from a pine forest ecosystem to drainage waters and the atmosphere, while on-site effects focused on the magnitude and extent of hydrologic fluxes of nutrients from burned litter to mineral soils and ground waters. Hydrologic nutrient fluxes from burned

LIBRARY U. OF I. - URBANA CHAMPAIGN

forest floors were evaluated from the nutrient contents of litter samples collected immediately after the fire and again after postburn rainfall of about 15 cm. The contents of total nitrogen, phosphorus and sulfur in burned forest floors were not significantly changed by the initial rainfall. Analysis of mineral soil collections before fire and after fire and rain indicated minor effects of fires on mineral soil chemical properties, despite variations in fire intensities and in postburn leaching conditions. The changes in total mineral soil carbon, nitrogen and phosphorus were small. No fire effects were observed on specific conductance, pH, or dissolved concentrations of ammonium, nitrates, phosphates, sulfates, chlorides, calcium, magnesium, potassium or sodium in ground waters collected from surface soil and subsoil horizons. No changes were noted in the chemical constituents of streams which could be attributed to the fire treatment. (Baker-FRC)

PONDING SURFACE DRAINAGE WATER FOR SEDIMENT AND PHOSPHORUS REMOVAL,
Snake River Conservation Research Center, Kimberly, ID.
M. J. Brown, J. A. Bondurant, and C. E. Brockway.
Transactions of the ASAE, Vol 24, No 6, p 1478-1481, November/December, 1981. 3 Fig, 3 Tab, 7 Ref.

Descriptors: *Sedimentation basins, *Phosphorus removal, *Agricultural runoff, Irrigation, Drainage water, Surface drainage, Ponds, Sediment control, Suspended sediment, Water pollution control, Erosion control, Runoff, Idaho, Sediment removal.

A 3400 cu m sediment retention pond receiving surface water runoff from 4050 ha of irrigated land in Idaho removed sediment and phosphorus at greater than design efficiency (50% of total sediment input) for the 5-year observation period, 1972-1976. Removal efficiencies were 65-76% for sediment and 25-33% for total P. Phosphorus passing through this pond was either soluble or attached to soil particles too small to settle without flocculation. Average daily flow through the pond during the irrigation runoff period, April-November, was 347 liters per sec, and average retention time was 2.7 hours. Removal efficiency generally increased with increasing flow rate. A stream flow of 340-453 liters per sec removed sediment most efficiently. Very high flow rates did not allow even silt particles to settle. Optimum sediment concentration was 20-750 mg per liter. (Cassar-FRC)

TOPSOIL MANAGEMENT OF MINED SOILS,
Science and Education Administration, Cheyenne, WY.
G. E. Schuman, and J. F. Power.
Journal of Soil and Water Conservation, Vol 36, No 2, March/April p 77-78, 1981. 23 Ref.

Descriptors: *Land reclamation, *Topsoil, *Resources management, *Strip mine wastes, *Strip mines, Soil management, Soil properties, Crop yield, Runoff, Infiltration, Watershed protection.

Federal and state laws require that strip mined land be reclaimed to a level of productivity equal to or greater than that which existed before the mining. Topsoil must be removed before the mining operation and redistributed over the graded overburden after the coal has been removed. Studies on necessary topsoil depth found maximum grass yields with a subsoil depth of 28 inches and a topsoil depth of 8 inches. Another study found topsoil depths of 8 and 16 inches to give good yields. Topsoil plays a major role in water infiltration; infiltration increases with topsoil depth. Some studies have found that the major portion of a root system is limited to the topsoil. Forage grown on reclaimed mine areas is generally of lower quality than that grown on adjacent land. This may be a result of topsoil stockpiling which causes shifts in soil fungal dominants and the loss of other microorganisms. In general, topsoil provides a good rooting medium, improves infiltration, reduces runoff, and encourages faster establishment of nutrient cycles. It also usually increases the species diversity of vegetational cover. (Small-FRC)

5. WATER QUALITY MANAGEMENT AND PROTECTION

5A. Identification Of Pollutants

EVALUATING MEDIUMS AND PLATING TECHNIQUES FOR ENUMERATING BACTERIA IN WATER DISTRIBUTION SYSTEMS,
Southern California Metropolitan Water District, LaVerne.
E. G. Means, L. Hanami, H. F. Ridgway, and B. H. Olson.
Journal of the American Water Works Association, Vol 73, No 11, p 585-590, November, 1981. 1 Fig, 7 Tab, 13 Ref.

Descriptors: *Bacterial analysis, *Culture media, Microbiological studies, Chlorination, *Drinking water, Water distribution, Membrane filtration, *Pollutant identification, Water analysis, Agar, Unchlorinated water, Comparison studies.

Media and plating techniques for bacterial enumeration were evaluated using 2 drinking waters, one chlorinated surface water and the other unchlorinated groundwater. Samples were collected bimonthly from June 1978 to September 1979. Media were plate count agar, R-2A low nutrient agar, and m-standard plate count agar. Incubation temperatures were either 20 or 35 C. The techniques were spread plate, pour plate, and membrane filtration. The m-standard plate count medium with membrane filtration recovered bacterial from the water systems most efficiently. The spread plate technique was better than the pour plate technique for counting the total and pigmented bacteria in both waters. The different media tended to select for particular subpopulations. There were also discrepancies in bacteria recovery efficiencies between the chlorinated and unchlorinated waters. In view of this evidence the pour plate method should be replaced with alternative methods for enumerating bacteria in water distribution systems. (Cassar-FRC)

EVALUATING STREAM STANDARD VIOLATIONS USING A WATER QUALITY DATA BASE,
Colorado State Univ., Fort Collins. Dept. of Agricultural and Chemical Engineering.
J. C. Loftis, and R. C. Ward.
Water Resources Bulletin, Vol 17, No 6, p 1071-1078, December, 1981. 4 Fig, 1 Tab, 9 Ref.

Descriptors: *Standards, *Water quality, *Variability, Effluent standards, Monitoring, Sampling, Model studies, Regulations, *Pollutant identification, Seasonal variation, Streams, *Sangamon River, *Illinois, Dissolved oxygen, Specific conductivity.

Two models (normal and nonparametric) for the behavior of a water quality random variable are reviewed. These models gave similar results when used with a water quality data base to describe the past behavior of a water quality variable relative to a stream standard and to evaluate apparent changes in the frequency of standard violations. They help to determine whether violations of standards are a result of natural variability or quality degradation. Cumulative density functions for water quality random variables were estimated using data from a routine grab sampling program, then were used to estimate the probability that a single grab sample will violate a given stream standard and to determine the anticipated number of violations in a given number of samples. Confidence limits about a point on the cumulative density function may be used to reflect the accuracy with which the sample estimate represents the true cumulative density function. The procedure, intended for use by state regulatory agencies, was illustrated using specific conductance and dissolved oxygen in the Sangamon River, Illinois. (Cassar-FRC)

Water SA, Vol 7, No 4, p 216-222, October, 1981. 4 Tab, 23 Ref.

Descriptors: *Swimming pools, *Microbiological studies, *Disinfection, Pollutant identification, Water treatment, Recreation facilities, Water quality, Public health, Bacteria, Coliforms, *South Africa, Chlorination, Drinking water, Mineral water.

Drinking waters, mineral waters, rheumatic treatment bath waters, and recreational hot and cold swimming pool waters in seven South African resorts were examined microbiologically. No viruses were isolated from recreational or drinking waters. Candida albicans was found in only 1 sample. Bacterial counts of most waters did not exceed accepted limits. Chlorine was effective as a disinfectant. It is suggested that drinking waters at resorts be monitored constantly and that children's swimming pools should have their own filtration-disinfection system. (Cassar-FRC)

DETERMINATION OF VOLATILE ORGANICS IN INDUSTRIAL AND MUNICIPAL WASTEWATERS,
California Analytical Lab., Sacramento.
J. L. Wilson.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-119090, Price codes: A05 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S4-81-071, December, 1981. 7 p, 5 Tab. 68-03-2033.

Descriptors: *Wastewater analysis, *Volatile organic compounds, *Gas chromatography, Electron capture gas chomatography, Industrial wastewater,

Municipal wastewater, Sample preservation, Halogenated hydrocarbon, *Organic compounds, Volatility.

Methodologies for the analysis of volatile organic compounds in industrial and municipal wastewater were developed and evaluated, using gas chromatography (GC) with flame ionization, electron capture, and Coulson detectors. Although no single GC column was found that gives complete chromatographic separation of all 36 of the test compounds, several packing materials were identified that provide good separation of all but a few compounds. All the test compounds were detected by one or more of the analytical approaches studied at levels of 1 ppb or less. The nonhalogenated compounds were not detected by Coulson or electron capture. Many of the compounds are detectable at levels of 0.1 ppb or lower. The addition of preservatives to reduce residual chlorine in aqueous samples was found to help maintain the chemical stability of the samples. The major limitation of all the analytical approaches investigated was the lack of specificity of detection. The flame ionization detector was the only detector that was able to detect the nonhalogenated compounds. However, it was the least specific of the detectors studied. For relatively clean wastewaters, a combination of the analytical methods was found to usually be both specific and sensitive. For grossly polluted wastewaters, interferences became such a severe problem that qualitative identification was not feasible. (Moore-SRC)

DETERMINATION OF HALOETHERS IN INDUSTRIAL AND MUNICIPAL WASTEWATERS,
Monsanto Research Corp., Dayton, OH.
P. L. Sherman, J. M. Kyne, R. C. Gable, J. V. Pustinger, and C. R. McMillin.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-123290, Price codes: A05 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S4-81-062, December, 1981. 5 p, 1 Fig, 4 Tab. 68-03-2033

Descriptors: *Haloethers, *Wastewater analysis, *Gas chromatography, *Chlorinated hydrocarbons, Municipal wastewater, Industrial wastewater, Ethers, Chemical analysis, Water analysis, Sample preservation.

The following haloethers were originally included in this study: 2-chloroethyl vinyl ether, bis(2-chloroisopropyl) ether, bis(2-chloroethyl) ether, bis(2-chloroethoxy) methane, 4-chlorophenyl phenyl ether, and bis(chloromethyl) ether. The 2-chloroethyl vinyl ether and bis(chloromethyl) ether were later deleted from the project because of extreme volatility and hydrolytic instability, respectively. A literature search was conducted to acquire published information on the hydrolytic stability of the haloethers, methods for the detection of haloethers in water, and methods for the isolation, concentration and analysis of haloethers. The workable method developed in this program for the analysis of haloethers in wastewater consisted of a liquid/liquid evaporators, a column chromatographic clean-up procedure using Florisil, another K-D evaporation of the fraction from the Florisil column, and subsequent analysis by gas chromatography using an electrolytic conductivity detector. Sample preservation was studied at various pH and residual chlorine levels and different temperatures. The stability of haloethers stored in acetone and in methanol was observed. (Moore-SRC)

SEWAGE SLUDGE PATHOGEN TRANSPORT MODEL PROJECT,
BDM Corp., Albuquerque, NM.
J. F. Dawson, K. E. Hain, B. McClure, R. E. Sheridan, and J. G. Yeager.
Environmental Protection Agency Project Summary EPA-600/S1-81-049, October, 1981. 5 p, 1 Fig.

Descriptors: *Computer models, *Pathogens, *Parasites, *Bacteria, *Viruses, *Sludge disposal, Wastewater treatment, Enteroviruses, Salmonella, Poliovirus, Ascaris, Mathematical models, Public health, Simulation, Fate of pollutants.

A computer model was developed to predict the numbers of specific pathogens that would be found in sewage sludge at various points during sludge treatment and application, along 13 defined pathways. These pathways describe the use of dried or liquid, raw or anaerobically digested sludge as a cropland fertilizer, dried raw sludge as an animal feed supplement, and composted sludge as a residential soil amendment. Three organisms were selected to represent the enteric pathogens most commonly found in sludge: Salmonella species were used to represent the bacteria; Ascaris species were used to represent parasites; and polioviruses were used to represent all enteric viruses. The model uses a compartment-vector approach in which a mathematical state represents a discrete point in a treatment or application pathway where pathogen populations are computed as a function of time. Within these compartments, mathematical process functions describe population changes due to environmental factors. Pathogen exchanges between compartments are described by transfer functions. The model permits user speciication of various parameters in both process and transfer functions, for simulation of a unique set of environmental conditions. The model has the additional capability of performing exposure risk calculations for environmental compartments specified by the model user at the time of model variable initialization. (Moore-SRC)

EVALUATION OF ELECTROMAGNETIC TERRAIN CONDUCTIVITY MEASUREMENTS FOR DETECTION AND MAPPING OF SALT-WATER INTERFACES IN COASTAL AQUIFERS.
University of South Florida, Tampa. Dept. of Geology.
T. Stewart.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-211459, Price codes: A04 in paper copy, A01 in microfiche. Publication No 60, September, 1981. 57 p, 27 Fig, 2 Tab, 28 Ref. OWRT A-043-FLA(1). 14-34-0001-1110.

Descriptors: *Remote sensing, *Geophysical surveys, Saltwater interfaces, Coastal aquifers, *Saline-freshwater interfaces, Electromagnetic waves, Conductivity, Measuring instruments.

In coastal areas salt-water intrusion represents a significant threat to water quality in coastal aquifer systems. The electromagnetic method evaluated in this study proved to be rapid, very inexpensive, and it yields results which agree well with geologic and geochemical surveys using direct sampling. The instrument reads directly in conductivity units, and the depth of investigation is constant for a particular spacing and orientation of the receiver and transmitter coils. Data can be obtained and interpreted by personnel with little technical training. Data interpretation normally involves contouring terrain conductivity maps, but quantitative solutions can be obtained where the geoelectric section can be reasonable approximated by a two-layer section. Some problems were experienced with interference. However interference sources usually were very localized and could be avoided. This study in two areas of Florida demonstrates that the EM conductivity method is very useful for rapid, inexpensive ground water surveys where the objective is to locate zones of conductive pore fluids at depths less than 30-40 meters. Although interpretation is indirect and qualitative, neither data aquisition nor interpretation require special training. This characteristic of the EM method makes it very suitable for use by agencies where highly-trained technical personnel are not available.

THE IDENTIFICATION AND TREATMENT OF BROMIDES AND TRIHALOMETHANES IN POTABLE WATER FROM THE PEARL RIVER AT JACKSON, MS: EVALUATION OF TOXICITY ON SPECIES DIVERSITY,
Mississippi State Univ., Mississippi State. Water Resources Research Inst.
G. D. Barnes, B. S. Dhillon, and A. S. Hume.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-211467, Price codes: A05 in paper copy, A01 in microfiche. Completion Report, December, 1981. 70 p, 20 Fig, 18 Tab, 48 Ref. OWRT B-028-MS(1). 14-34-0001-1239.

Descriptors: *Water pollution, *Trihalomethanes, Silver bromide, Silver bromate, *Bromides, Potassium bromide, Species diversity, Mean numbers of organisms, Community composition, Zooplankton, Decay rates of trihalomethanes, *Phytoplankton, Toxicity, Water treatment, Potable water, *Pearl River, *Jackson, Mississippi, Daphnia, Cyclops.

Significant differences in a completely randomized block design were found in species diversity (d) and mean numbers of phytoplankton in microcosms by the following treatments when compared to a control: total trihalomethane levels (1, 10, 1000 and 100,000 ppb); potassium bromide levels (1, 10 and 1000 ppb); silver bromide levels (1, 10, 1000, 10,000 and 100,000 ppb) and silver bromate (1, 10 and 1000 ppb). Toxic threshold levels for algae were between the two highest levels in THM and silver bromide respectively. Daphnia sp. and Cyclops sp. mortality increased with increasing levels of treatments: total trihalomethanes (1, 10, 100 and 1000 ppb); silver bromides (1, 10, 1000 and 10,000); silver bromates (1, 10, 1000 and 10,000). The high level of silver bromate was extremely toxic in both experiments to Daphnia and Cyclops. Percent decay rates for chloroform, bromodichloromethane, chlorodibromomethane and bromoform were similar at all time intervals throughout the study. By 11.3 hrs., approximately fifty percent of all the trihalomethanes were depleted from the microcosms. From computer projected decay rates, chloroform and bromoform were depleted from the microcosms by 80 hrs.

MEMBRANE FILTER METHOD FOR ENUMERATION OF ACINETOBACTER CALCOACETICUS FROM ENVIRONMENTAL WATERS,
Rhode Island Univ., Kinston. Dept. of Microbiology.
S. J. LaCroix, and V. J. Cabelli.
Applied and Environmental Microbiology, Vol 43, No 1, p 90-96, 1982. 5 Fig, 2 Tab, 31 Ref.

Descriptors: *Membrane processes, *Bacteria, Ponds, Filtration, *Bacterial analysis, Separation techniques, Lakes, Nutrients, Microbiological studies, Acinetobacter calcoaceticus, Pathogenic bacteria, Pollutant identification.

The aim of this study was to develop a selective-differential procedure for the quantification of Acinetobacter calcoaceticus as the first step in better defining the ecology of the organism. The procedure developed uses a mineral medium, with sodium acetate and potassium nitrate as the carbon and nitrogen sources, respectively. The recovery of A. calcoaceticus was enhanced through the introduction of formic acid, which also inhibited background growth. After incubation at 30 degrees C for 46 hr, fermentation and cytochrome oxidase tests were performed on the colonies as they appeared on the membrane. Background microbial growth decreased on the average by 1.77 orders of magnitude. An essentially quantitative recovery relative to that on nutrient agar spread plates was obtained from freshly prepared suspensions of eight A. calcoaceticus strains in filter sterilized pond water at 15 and 22 degrees C. With the three remaining strains markedly reduced relative recoveries were obtained. However, these three strains, in contrast to the first five, not only did not grow,

LIBRARY U. OF ILLINOIS CHAMPAIGN

but also decreased in number in the eutrophic, filter sterilized pond water. The confirmation rate of presumptive A. calcoaceticus colonies was 95%, whereas 8% of the presumptively negative colonies were A. calcoaceticus. Densities of A. calcoaceticus in freshwaters ranged from less than 1 to 79,000 organisms per 100 ml water and were about 1,000,000 organisms per 100 ml in raw sewage. (Baker-FRC)

A SIMPLE MICRODETERMINATION OF POLYMER FLOCCULANTS (POLYACRYLAMIDES AND GUAR) IN MINE WATER,
Anglo American Research Lab., Johannesburg (South Africa).
E. Jungreis.
Analytical Letters, Vol 14, No A14, p 1177-1183, 1981. 3 Tab, 8 Ref.

Descriptors: *Mine drainage, *Chemical analysis, Filtration, Membrane filters, Filters, Membrane processes, *Polymers, Guar, Polyacrylamides, Flocculation, *Wastewater analysis.

A method is presented for the microdetermination of polymer flocculants in mine water by measuring the laminar flow rate through a membrane filter under vacuum. The procedure calls for filtering the mine water sample through an 8.0 micrometer millipore filter, measuring the pH, and filtering 50 ml of this pretreated sample through a 0.22 micrometer 25 mm diameter millipore filter under vacuum. The filtration time is measured. A calibration graph is prepared at the same temperature, same pH, same vacuum conditions and the same filtering system, with freshly prepared polymer flocculant solution of the same kind. The concentration of the unknown is determined from the time-concentration plot. The precision of the method is acceptable. (Baker-FRC)

DETERMINATION OF TRACE INORGANIC POLLUTANTS (CU, PB, CD, ZN) IN WATERS BY DIFFERENTIAL PULSE ANODIC STRIPPING VOLTAMMETRY AT A ROTATING MERCURY FILM ELECTRODE (DOSAGE DE MICROPOLLUANTS MINERAUX DES EAUX (CU, PB, CD, ZN) PAR VOLTAMPEROMETRIE DE REDISSOLUTION ANODIQUE IMPULSIONNELLE SUR ELECTRODE TOURNANTE A FILM DE MERCURE),
Parisien Lab. Regional de l'Est, Le Bourget (France).
M. Bouzanne.
Analysis, Vol 9, No 10, p 461-467, December, 1981. 5 Fig, 11 Ref. English summary.

Descriptors: *Chemical analysis, *Water quality, *Heavy metals, Metals, Electrodes, Electrochemistry, Chemical interference, Dissolved oxygen, Natural waters, Copper, Lead, Cadmium, Zinc.

Various anodic stripping techniques seem promising for rapid, simple determination of trace inorganic pollutants, especially heavy metals, in natural waters. Differential pulse anodic stripping voltammetry using a preconcentrated phase is inherently more sensitive than direct electrochemical methods such as pulse polarography. A rapid deoxygenation apparatus was developed for use with this method, which was then applied for heavy metal determination in 500 samples of various natural waters. Operating conditions such as pulse duration, electrolysis potential, and final potential depend to some extent on the nature and concentration of the supporting electrolyte. The duration of electrolysis, electrode rotation speed, and measurement scale were adjusted after a preliminary tracing was obtained. Use of an internal standard is recommended rather than a calibration curve because of possible variations between samples due to the presence of traces of surfactants or dissolved oxygen and alterations in the mercury distribution. Interference due to the formation of intermetallic compounds in simultaneous determinations can be eliminated by addition of suitable reagents such as gallium and germanium salts. Prior oxidation with potassium persulfate or UV photolysis can eliminate interference by traces of dissolved organic compounds. At the microgram per liter level, the coefficient of variation for eight successive determinations of lead, cadmium and copper was 1-1.5%, depending on the element examined. For a reasonable electrolysis time of 15 min, detection limits of 10 ng/l were achieved for lead and 5 ng/l for copper and cadmium. (Carroll-FRC)

ENTEROTOXIGENIC BACTERIA IN FOOD AND WATER FROM AN ETHIOPIAN COMMUNITY,
Sveriges Lantbruksuniversitet, Uppsala. Dept. of Bacteriology and Epizootology.
S. F. H. Jiwa, K. Krovacek, and T. Wadstrom.
Applied and Environmental Microbiology, Vol 41, No 4, p 1010-1019, April, 1981. 1 Fig, 5 Tab, 57 Ref.

Descriptors: *Pollutant identification, *Pathogenic bacteria, *Bacterial analysis, Water pollution, Developing countries, Enteric bacteria, E. coli, Isolation, Separation techniques, Human diseases, Coliforms, Foods, Public health, *Ethiopia.

Forty of 213 bacterial isolates from Ethiopian food and natural water samples were capable of producing heat-labile enterotoxin (LT). Among the LT-producers Escherichia coli, Enterobacter, Klebsiella, Serratia, and Proteus were present. Enterotoxigenic isolates from food included oxidase positive strains of Aeromonas, Pseudomonas, Achromobacter, Flavobacterium, and Vibrio. LT-enterotoxigenic species from food and water samples included Enterobacter, Acinetobacter, Klebsiella, Proteus, Providencia, and Serratia. Several isolates gave positive reactions in Chinese hamster ovary cell tests and induced fluid accumulation in rabbit ileal loops. After storage in trypticase soy broth with glycerol at -70 degrees C for 9 months, only about 33% of the oxidase-positive strains were still LT enterotoxigenic. None of the E. coli isolates possessed K88, K99 or colonization factor antigen. Although this study showed that food and water contained enterotoxigens of the same species as those isolated from infantile diarrhea cases, no correlations were made between these pathogens and the incidence of infantile diarrhea in developing countries. INFLUENCE OF DILUENTS, MEDIA, AND MEMBRANE FILTERS ON DETECTION OF INJURED WATERBORNE COLIFORM BACTERIA,
Montana State Univ., Bozeman. Dept. of Microbiology.
G. A. McFeters, S. C. Cameron, and M. W. LeChevallier.
Applied and Environmental Microbiology, Vol 43, No 1, p 97-103, 1982. 3 Fig, 2 Tab, 44 Ref.

Descriptors: *Bacteria, *Drinking water, Water analysis, Filtration, Membrane processes, Membranes, *Coliforms, Waterborne bacteria.

The recovery of coliforms both before and after substantial cellular injury in drinking water is examined with respect to the composition, exposure time, and temperature of the diluents; the composition of various media commonly used in water quality testing; and the surface pore morphology of membrane filters at 35 degrees C. Pure cultures of Escherichia coli, Klebsiella pneumoniae, Enterobacter aerogenes, and Citrobacter freundii were injured in water from a dead end section of the Bozeman, Montana, distribution system. The addition of peptone or milk solids to diluents and low temperatures of 4 degrees C maximized the recovery of injured cells but did not significantly affect undamaged cells. High efficiencies of recovery of control cells were noted on most media tested, but recoveries of injured cells ranged from 0 to nearly 100%. Less than 30% of the injured cells were recovered by most of the media commonly used in water analysis. This was done in part to the sensitivity of injured bacteria to deoxycholate concentrations greater than 0.01%, whereas control cells were unaffected by 0.1%. A negligible effect of membrane filter surface pore morphology on total coliform recoveries was noted at 35 degrees C. These findings support the development of new methodologies, allowing a more complete enumeration of injured coliforms in potable water and providing more accurate and dependable water quality information. DETERMINATION OF TRACE ELEMENTS IN SEAWATER BY NEUTRON ACTIVATION ANALYSIS AND ELECTROCHEMICAL SEPARATION,
Oslo Univ. (Norway).
K. Jorstad, and B. Salbu.
Analytical Chemistry, Vol 52, No 4, p 672-676, April, 1980. 4 Fig, 4 Tab, 9 Ref.

Descriptors: *Trace elements, *Water analysis, *Neutron activation analysis, Electrochemistry, Chemical reactions, Heavy metals, *Seawater, Electrolysis, Separation techniques, *Pollutant identification, Water pollution, Radioactive tracers, Radioisotopes.

In order to reduce the respective disadvantages of the individual methods, neutron activation analysis has been combined with electrodeposition on a mercury electrode to concentrate traces of reducible metals, leaving interfering elements in solution. This combination provides a useful multielement method for the determination of 28 elements in seawater. Samples which have been freeze-dried and irradiated are dissolved in dilute nitric acid and electrolyzed for 1 hour. Silver, arsenic, gold, cadmium, cobalt, chromium, iron, mercury, gallium, lanthanum, molybdenum, antimony, selenium, and zinc can be determined from the radioactive species deposited on the mercury cathode. After a radioactive decay time of 2 weeks, the following 14 elements can be determined by measuring the activities in the residual solution: barium, bromine, calcium, cerium, cesium, europium, sodium, rubidium, scandium, samarium, strontium, thorium, uranium, and ytterbium. Since only radioactive species deposited on the cathode or left in the solution are being measured, technical grade reagents can be used. In order to obtain a reproducible electrolysis, radioactive tracers have been used to study the decrease of element concentrations in solution as a function of time of electrolysis, the influence of the initial element concentration on the rate constant K, the effect of cathode material, and the effect of the pH in solution. The technique may be used for multielement analysis of other samples having a high content of interfering elements which are not deposited on the electrode, such as samples of biological or geologic origin. AUTOMATIC MEASURING STATION FOR CONTINUOUS MONITORING OF RIVERS,
Passavant-Werke Michelbacher Huette, Aarbergen (Germany, F.R.).
H. B. Kloppel.
Water Science and Technology, Vol 13, No 11/12, p 683-686, 1981. 1 Fig.

Descriptors: *Monitoring, *Water quality, *Automation, Computers, Water management, Rivers, Data acquisition, Data collections, Turbidity, Hydrogen ion concentration, Dissolved oxygen, Conductivity, Wastewater treatment, *Effluents.

A measuring station is described which was developed for the constant monitoring of rivers or water with similar characteristics. It is equipped for automatic cleaning and calibration and can be monitored remotely by means of an integrated computer via MODEM and telephone connection. The parameters for water temperature, pH, dissolved oxygen, conductivity and turbidity are measured. The computer collects the test data. It carries out preliminary data processing and stores the data

until it is called up by telephone. In addition the computer accepts the commands for controlling the station via to a telephone connection. It transfers the commands to the control unit of the station, and reports back the operating condition of the station via telephone. The station can also be operated as an independent functional unit without a computer, and as such can be used for monitoring the final effluent of a sewage treatment plant without much maintenance. The measured values are then transmitted separately via cable to the control center of the treatment plant itself. The measuring station is provided with very effectively operating equipment for the automatic cleaning and calibration of the sensors so that the station can operate without supervision for 4 weeks. Siegrist G.m.b.H., Hamburg (Germany, F.R.).
H. Fuhrmann.
Wasser, Luft und Betrieb, Vol 25, No 12, p 25-28. 1981. 8 Fig, 4 Ref. (No English Summary).

Descriptors: *Chemical analysis, *Solvents, *Measuring insruments, Industrial water, Indusrial wastewater, Organic compounds, Chemical industry, Separation techniques, Trace levels.

A flexible second generation measurement system was developed which can be applied to the measurement of organic solvents in air and water. The measurement principle is based on changes in the elecrical conductivity of heated gas semiconductors due to the presence of adsorbed reducing materials. Systems applicable to water include membrane-sensor systems immersed directly in the liquid to be measured and connected to the evaluation apparatus by cable; membrane systems immersed in the liquid to be measured, with continuous measurement provided by diffusion rate dilution with clean air, and continuously operating phase exchange systems with evaluation by gas sensors. The latter system avoids problems due to water contaminants in that only the volatile solvents are transferred into the gas phase. Range selection and calibration curves can be used to measure individual and total components. These instruments are particularly suitable for industrial applications. (Carroll-FRC)

CHLORIDE DETERMINATION IN AUTOMATED WATER COMPOSITION MONITORING (CHLORIDBESTIMMUNG IN DER AUTOMATISIERTEN WASSERBESCHAFFENHEITSKONTROLLE),
Institute fuer Wasserwirtschaft, Berlin (German D.R.).
H. Heitmann.
Wasserwirtschaft-Wassertechnik, Vol 31, No 10, p 341-342, 1981. 6 Ref. (No English Summary).

Descriptors: *Chlorides, *Chemical analysis, *Titration, Automation, Salinity, *Monitoring, Drinking water, Industrial water, River water, Saale River, *Elbe River, Potentiometry, Saline water intrusion, Germany.

Chloride levels in drinking water should not exceed 250 mg/l, since higher concentrations give a brackish taste. Chloride in industrial water corrodes iron, and chloride monitoring is also necessary as an indicator of saltwater intrusion. Possible methods of automated chloride monitoring include continuous potentiometric measurement of chloride ion activity with an ion-sensitive electrode and automated potentiometric titration of chloride ions with silver nitrate solutions. The former method is easier, but the latter method is more accurate, and therefore each of these methods is most suitable for specific applications. Use of continuous potentiometric chloride measurement is advantageous only where great accuracy is not required, for example for saltwater intrusion monitoring, so that an alarm can be sounded if a specific chloride level is exceeded. It is less useful for effluent monitoring because of possible interference by sulfide, bromide, iodide, cyanide and thiosulfate ions, as well as changes in the total salt content and temperature of the water. Automated electrode cleaning and calibration could improve accuracy beyont the presentplus or minus 15%. automated titration equipment is available which has a sample collection timing device. Mixing effects can introduce errors, especially in turbid samples, but can be controlled by slowing the rate of titration. Automated titration for determining the chloride input from the Saale into the Elbe iver over a number of years gave accuracy comparable to that of laboratory titration, (Carroll-FRC)

Wasserwirtschaft-Wassertechnik, Vol 31, No 10, p 337-340, 1981. 5 Fig, 9 Ref. (No English summary).

Descriptors: *Activated sludge process, *Turbidity, *Process control, Sludge solids, Wastewater treatment facilities, Effluents, Sludge excess, *Monitoring, Automation, Measuring instruments.

The characteristics most frequently used for evaluating wastewater treatment effluent quality, such as BOD and filterable materials, are not suitable for rapid measurement, within a time period suitable for process control utilization. Other possible characteristics, such as chemical oxygen demand and total organic carbon, are not directly linked with the functioning of the activated sludge plant. Turbidity measurement has not been widely used for rapid estimation of effluent quality because of the difficulty of establishing a definite relationship between turbidity and other quality criteria in different waters. Sludge discharge was a frequent problem at the Wahren wastewater treatment plant. An attempt was made to monitor the occurrence of this phenomenon using a continuous light scattering turbidimeter, Nephelon II. Relatively close correlations were found between turbidity values, activated sludge content and BOD. Correlations were poor when large numbers of hydrophobic particulates were present following heavy rain and when incomplete biological purification was occurring, but errors were on the conservative side in these cases. If hydraulic conditions are favorable, measurements may be employed to control the operation of excess sludge pumps as long as safeguards against over-running are added. (Carroll-FRC)

THE UNTERWESER AUTOMATIC WATER QUALITY MEASUREMENT SYSTEM,
H. Kunz.
Water Science and Technology, Vol 13, No 11/12, p 657-662, 1981. 6 Fig, 2 Tab, 4 Ref.

Descriptors: *Water quality, *Monitoring, *Weser River, Germany, Data acquisition, Automation, Water management, Oxygen, Acidity, Powerplants, *Wastewater, Mixing, Tidal rivers, Heated water, *Nuclear powerplants, *Tidal effects.

This paper describes the requirements placed on the Unterweser nuclear power plant (KKU) measurement system, the technical configuration, experience and results. The nuclear power plant operator must control his plant so as to remain within specified limits. The water authority responsible requires proof of this and carries out checks on the plant. In addition to thee temperature, the oxygen content, the conductivity and to a limited extent the pH value are also calculated. The measuring stations in the Unterweser have been placed as far out into the deep navigation channel as shipping permits because this offers the best point for presenting the applicable water quality conditions. The measurement station only records the values and transmits them to a central station when polled by radio. The stationary KKU water quality measurement system has available a fast measurement vessel as well as two meteorological measuring stations. These systems can both collect and record data themselves as well as be integrated in the data flow controlled from the central station. In contrast to tidal-free waters, the water level as well as the flow rates periodically vary with the tide, and sea water flows in. One and the same body of water passes a discharge point several times and is thus charged with waste water many times. Waste water discharged into the river may be carried by the tidal flow far beyond the discharge point. This complicated transporting and mixing process demands sophisticated measuring equipment to obtain data needed for control, monitoring and securing evidence of falling quality. (Baker-FRC)

CONTINUOUS WATER QUALITY MONITORING SYSTEM USING TELEMETRY IN THE CITY OF OSAKA,
Japan Sewage Works Bureau, Osaka.
K. Nanbo, and R. Kunogi.
Water Science and Technology, Vol 13, No 11/12, p 639-644, 1981. 3 Fig, 1 Tab.

Descriptors: *Water quality, *Monitoring, *Automation, Telemetry, Computers, Data acquisition, *Osaka, *Japan, Networks, Performance evaluation, *Wastewater facilities.

This paper summarizes the monitoring system used for water quality control in the city of Osaka, Japan, and lists items of importance for ensuring that the system operates at maximum efficiency and provides exact data. The central monitoring system is connected with the river monitoring stations, the sewage treatment plant monitoring stations and the factory monitoring stations by telemetry and collects data from them. Nine river, three sewage, and six factory monitoring stations have already been installed, and plans exist for 1, 10, and 4 additional stations, respectively. The central monitoring station is connected with each river and sewage treatment plant monitoring station through an allotted communication circuit and with factory monitoring stations through the public communication circuit. Data are collected every 5 minutes from river stations, every hour from sewage treatment plant stations and every day from factory stations, by a polling system. Various kinds of instruments are installed for telemetry, data logger and input-output of data in the central monitoring station. Proper maintenance is indispensable to get the most efficient operation from the equipment. It is hoped that the information being gained will aid the establishment of automatic water quality monitoring systems. (Baker-FRC)

tion sources, Watershed protection, Chemical analysis, Dissolved oxygen, Turbidity, *Waterways, *France.

In 1971 automatic monitoring of waterways was introduced into the Artois-Picardie area in northern France. This monitoring was found to be insufficient after a few years, and automatic monitoring of sewage was introduced. From 1975 on, two mobile stations were used to observe the natural conditions in the waterways of the catchment area and those affected by sewage pollution. The results showed the influence of nocturnal discharges from a cheese dairy upstream of the recording station on the quality of a small waterway. From 8 PM to 6 AM a significant increase of organic matter was noted, and a marked decrease in dissolved oxygen content. Subsequently an automatic Philips total oxygen demand meter and turbidimeters were tested on site with treated sewage and sewage containing industrial effluents. These were then included in the overall monitoring system in 1978 and 1979, with the building of four sewage monitoring stations. The results obtained by the end of 1980 concern 25 different types of discharge: paper mill, chemical, breweries, canning factories, iron and steel, domestic sewage and others. Plans for the future are briefly discussed. (Baker-FRC)

EVALUATION OF WATER QUALITY DATA RECEIVED BY AUTOMATIC CONTROL STATIONS AT THE TELTOW-CANAL IN BERLIN (WEST),
Technische Univ., Berlin (Germany, F.R.). Inst. fuer Chemieingenieurtechnik.
J. Schafer, H. Schumann, W. Niemitz, and U. Wiesmann.
Water Science and Technology, Vol 13, No 11/12, p 663-670, 1981. 7 Fig.

Descriptors: *Data collections, *Water quality, Automation, Monitoring, Canals, *Germany, *Teltow Canal, Berlin, *Effluents, Powerplants, Computers, Municipal sewage, Wastewater facilities.

The Teltow Canal is now one of the most heavily loaded waterways in Germany and contributes greatly to eutrophication of the lower Havel and the Havel lakes. This paper presents a first evaluation of water quality data from six automatic control stations along the canal. Mean values are given for each half year from 1972 through 1979 for concentrations of dissolved oxygen, temperature, conductivity and acidity. Changes in the distribution functions are given for diurnal mean values of oxygen concentration. A continuous degeneration of water quality over this time period was easily demonstrated. A special computer program was adapted to show the local and temporal changes in the data collected. Some of the results are presented as isolines for oxygen concentration and temperature. The increase in loading of the canal over the years was dramatic after the introduction of effluents from a new sewage treatment plant and another large power station. (Baker-FRC)

DETECTION AND MAPPING OF INSOLUBLE SINKING POLLUTANTS,
Rockwell International, Newbury Park, CA.
R. A. Meyer, M. Kirsch, and L. F. Marx.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-105586, Price codes: A05 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-198, October, 1981. p, 5 Fig, 1 Tab. 68-03-2648.

Descriptors: *Water pollution, *Conductivity, *Acoustics, *Mapping, *Monitoring, *Hazardous materials, Carbon tetrachloride, Immiscibility, Solubility, Computers, Cleanup operations, Spills, *Pollutant identification.

Some of the hazardous materials spilled into rivers, streams, or lakes are immiscible, slightly soluble, and denser than water. These sinking pollutants must be detected at once, and their locations must be mapped to initiate cleanup operations and minimize impacts. An electrical conductivity monitoring system was developed to detect the rrival of sinking pollutants at the bottom of a watercourse. The submersible monitor uses a cyclically purged electrical conductivity probe capable of long-term deployment even when partially buried in sand or silt. The submersible unit, which is battery powered, will transmit the conductivity data to the shore-base receiver by means of ultrasonics. The unattended design life of the monitor is 1 year. A commercial 200-kHz depth-finder system has been extensively modified and tested for use in an underwater acoustic mapping system to locate pools when a spill of a sinking pollutant is known to have occurred. Laboratory tests indicate that the system is capable of resolving the echoes from the surface of a 1-cm deep layer of carbon tetrachloride from those returning from a hard, sandy, or muddy bottom. Field testing revealed few precursor echoes that might mask or interfere with the detection of an echo from a pollutant pool. Return echoes were evaluated by 16-mm motion picture photography, and a computer-based comparator-counter technique has been developed for data management. (Moore-SRC)

CONSTITUENTS OF HIGHWAY RUNOFF; VOLUME II, PROCEDURAL MANUAL FOR MONITORING OF HIGHWAY RUNOFF,
Envirex Inc., Milwaukee, WI.
M. K. Gupta, R. W. Agnew, and T. L. Meinholz.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-241903, Price codes: A07 in paper copy, A01 in microfiche. Federal Highway Administration Report No FHWA/RD-81/043, February, 1981. 121 p, 36 Fig, 9 Tab, 34 Ref, 3 Append. DOT-FH-11-8600.

Descriptors: *Highways, *Water pollution sources, *Monitoring, *Runoff, *Water sampling, Flow measurement, Precipitation, Storm runoff, Land use, Site selection, *Highway effects, Environmental effects.

This manual has been prepared for use by highway department personnel to evaluate highway runoff. It contains detailed procedures for establishing and conducting a monitoring program and evaluating the collected data. There are a number of factors affecting the quality of the runoff that must be actively monitored for any site. Primary among these are traffic characteristics, highway operation and maintenance practices, precipitation characteristics, and the accumulation of pollutants on the highway. Other factors which must be noted because of their relevance to the quality of runoff include: adjacent land usage, right-of-way characteristics, roadway alinement, vertical plane, alinement of the highway, and pavement conditions. The steps required in establishing a successful monitoring program include: selection of a suitable site; planning a monitoring program; installing the monitoring equipment; maintenance and monitoring procedures; and evaluation and application of the results. A simple program may involve monitoring a single runoff event using manual sampling and flow monitoring techniques. A more complex program might involve monitoring events for an entire year or longer automated equipment. (Moore-SRC)

THE EFFECT OF STORAGE BY FREEZING ON DISSOLVED INORGANIC PHOSPHATE, NITRATE AND REACTIVE SILICATE FOR SAMPLES FROM COASTAL AND ESTUARINE WATERS,
Department of the Environment, Sidney (British Columbia). Inst. of Ocean Sciences.
R. W. Macdonald, and F. A. McLaughlin.
Water Research, Vol 16, No 1, p 95-104, January, 1982. 11 Fig, 4 Tab, 15 Ref.

Descriptors: *Sample preservation, *Nutrients, *Storage, Freezing, Silicates, Estuaries, Nitrates, Phosphates, Water sampling, Filtration, Thawing, Water analysis.

The effect of storage methods on stability of nutrients in coastal and estuarine waters was investigated. Parameters compared were freezing, quick freezing, filtering, and storage time. For phosphate, quick freezing produced better accuracy and precision in analysis. Filtration was necessary for turbid samples. Thaw time was not significant; storage time was significant for two of four samples, but examination of the data showed no clear trends. For nitrates, freezing was satisfactory; filtration was not necessary. Quick freezing slightly reduced the number of maverick samples. Freezing slightly decreased nitrate (1.6% for saline samples and zero for low salinity samples) and increased variance. Thaw time had no effects. In silicate determination, freezing was satisfactory for storage of saline water samples but not for low salinity estuarine samples, in which 5-15% of silicate was lost even after 24 hours that time. Quick freezing was better than regular freezing for the saline samples; filtering was not required. Samples should be analyzed for all three nutrients within two months after collection to limit variance caused by storage. (Cassar-FRC)

SURROGATE PARAMETER ANALYSIS FOR ORGANIC PRIORITY POLLUTANTS,
Virginia Univ., Charlottesville. Dept. of Civil Engineering.
C. E. Parker.
Journal Water Pollution Control Federation, Vol 54, No 1, p 77-86, January, 1982. 10 Fig, 33 Ref.

Descriptors: *Environmental effects, *Hazardous materials, *Toxins, Organic compounds, Wastewater, Water pollution sources, Bacteria, Cultures, Oxygen uptake, Adenosine triphosphatase, Pollutant identification, Water quality control.

In this paper the concept of using two microbial activities, adenosine triphosphate (ATP) and oxygen uptake, to quantify the strength of toxics in wastewater through a surrogate parameter is explored. Integrating short-term activity-time curves for various toxin concentrations and then correlating the activity-area curves with toxin concentration seem to be conceptually sound and offer one possible methodology for establishing a surrogate measurement of toxicity. The response of an ATP pool for a bacterial population to a toxic substance differs significantly from oxygen utilization. Because changes in the ATP pool are rapid and depend on the physiological state of the organism, standardization of the growth phase and of environmental conditions are essential. To eliminate the effect of the physiological state and to minimize fluctuations in the ATP pool, the ATP response to toxins is best measured during engogenous respiration and without substrate additions. The ATP activity response versus time for the endogenous culture could then reflect inhibition by the toxin. Toxins with the same activity-time response patterns may be quantified on the basis that equivalent areas represent short-term equivalent toxic effects. It has been shown that for several toxins the areas from activity-time plots for a bacterial culture can be related to toxin concentration. The ATP response is the more sensitive of the two activity measurements. Development of a bacterial bioassary procedure for surrogate toxin measurements will require the use of a pure culture. WATER QUALITY PATTERNS DURING A STORM ON A MALL PARKING LOT,
State Univ. of New York at Syracuse. Coll. of Environmental Science and Forestry.
P. E. Black.

Water Resources Bulletin, Vol 16, No 4, p 615-620, August, 1980. 6 Fig, 2 Tab, 13 Ref.

Descriptors: *Urban runoff, *Nonpoint pollution sources, *Runoff, Fate of pollutants, Parking lots, Water pollution sources, Paving, Water quality, Rainfall-runoff relationships, Ammonium, Metals, Subsurface runoff, Streams, Conductivity, Water temperature, Surburban malls, New York.

Rainfall, surface runoff, and subsurface drainage plus streamflow upstream and downstream of a suburban New York mall parking lot were intensively sampled during and after a thunderstorm on June 18, 1978. Prior to the 11.4 mm which fell within less than 1.5 hours, no rain had fallen for 4 days. Ammonia-N concentrations were high (up to 2.5 mg per liter) in parking lot runoff, a result of precipitation which contained up to 2.0 mg per liter ammonia-N. Surface runoff had a peak in conductivity during the rainfall and returned to prestorm levels by the end of the study period. Initial runoff appeared gray and nearly opaque. Nine constituents (K, Mn, Fe, P, Pb, Zn, Mg, Ca, and Na) showed a peak in surface runoff between 45 and 60 min after the rain started, declined to a low at 75 min, and returned to prestorm values by 105 min. Drainage from subsurface drains was brown in color and had a strong odor. In the receiving stream, water temperature increased and conductivity decreased during the beginning of the storm and returned to prestorm levels after 5 hours. (Cassar-FRC)

OCCURRENCE AND DISTRIBUTION OF CHEMICAL POLLUTANTS IN LAKE MARIUT, EGYPT. II. HEAVY METALS,
Alexandria Univ. (Egypt). Dept. of Oceanography.
M. A. H. Saad, A. A. Ezzat, O. A. El-Rayis, and H. Hafez.
Water, Air and Soil Pollution, Vol 16, No 4, p 401-407, 1981. 1 Fig, 3 Tab, 4 Ref.

Descriptors: *Heavy metals, *Lakes, Zinc, Copper, Manganese, Iron, Cadmium, *Distribution patterns, Water pollution sources, *Lake Mariut, *Egypt, Industrial wastes, Fish.

This study deals with the occurrence and seasonal distribution of heavy metals in the water and Tilapia fish of Lake Mariut. Six stations were chosen to represent different regions in Lake Mariut. Two additional stations were selected at the connections of Umum Drain and Qala Drain with the lake. The mean concentrations of zinc, copper, iron, manganese, and calcium in the lake water were 10.9, 4.2, 19.1, 26.2, and 0.62 micrograms/liter, respectively. The monthly average values of zinc varied from a minimum of 3.4 micrograms/liter in October 1978 to a maximum of 20.5 micrograms/ liter in May 1979. The metal concentrations in the fish gave higher values for the liver than the stomach concerning zinc, copper, iron, and cadmium. The mean concentrations of zinc, copper, iron, and manganese found in the stomach were markedly higher than those present in the edible flesh of the flank region and the caudal peduncle. (Baker-FRC)

BIOGENIC AND ABIOGENIC POLYNUCLEAR AROMATIC HYDROCARBONS IN SEDIMENTS FROM TWO REMOTE ADIRONDACK LAKES,
Department of Energy, New York. Environmental Measurements Lab.
Y. L. Tan, and M. Heit.
Geochimica et Cosmochimica Acta, Vol 45, No 11, 9 Fig, 7 Tab, 39 Ref.

Descriptors: *Aromatic compounds, *Lakes, *Sediments, Polynuclear aromatic hydrocarbons, Hydrocarbons, *Sagamore Lake, *Woods Lake, *New York, Perylene, Lake sediments, Organic matter, Abietic acid, Retene, Terpenes, Organic compounds, Water pollution sources, Fate of pollutants.

Polynuclear aromatic hydrocarbons (PAH) were determined in sediment cores from Sagamore Lake and Woods Lake, New York, remote from industrial activities. The composition and distribution of the parental PAH in the sediment indicate that the source of PAH in the surface is anthropogenic combustion of fossil fuels. Forest fires were ruled out as a source because sediment cores revealed no trace of the only known fire, which occurred about 80 years ago. All parental PAH, with the exception of perylene, decreased in concentration with depth in the cores. Perylene levels increased dramatically with depth to a maximum at 35 cm and decreased at greater depths. It has been suggested that perylene is transformed from natural precursors in the reducing environment, but the identity of these precursors was not investigated in this study. Concentrations of nonparental PAH were relatively uniform throughout the sediment cores. Some of the products identified were retene and other intermediates in the conversion of abietic acid to retene and hydrochrysenes and hydropicenes derived from pentacyclic triterpenes. Abietic acid is a major component of pine resins, and the pentacyclic triterpenes are widely distributed in higher plants. Concentrations of all parental PAH, except perylene, were higher in Woods than in Sagamore. The sediment densities and sedimentation rates are higher in Sagamore. (Cassar-FRC)

ACIDIC PRECIPITATION: CONSIDERATIONS FOR AN AIR QUALITY STANDARD,
Brookhaven National Lab., Upton, NY.
L. S. Evans, G. R. Hendrey, G. J. Stensland, D. W. Johnson, and A. J. Francis.
Water, Air, and Soil Pollution, Vol 16, No 4, p 469-509, 1981. 3 Fig, 3 Tab, 83 Ref.

Descriptors: *Water quality, *Acid rain, Rainfall, Air pollution, Acidic water, Hydrogen, Fish, Water pollution sources, *Water pollution effects, Ecological effects.

This paper discusses the relationship between precipitation acidity and receptor effects. First, the existence of acidic precipitation is documented, including temporal and spatial variability. A review of receptor characteristics is presented, along with responses to acidic precipitation, describing links between acidic precipitation and enviornmental effects where wuch links are known. Information gaps are highlighted. Finally the possibility of establishing a critical threshold for precipitation acidity is evaluated, which can serve as a meaningful standard to protect to protect terrestrial and/or aquatic biota. The chief anions accounting for the acidity in rainfall are nitrate and sulfate. Greater nutritional benefits are derived from acid rain by agricultural rather than forest systems, when considering soils alone. Acid deposition has caused acidification of fresh waters of southern Scandinavia, southwestern Scotland, southeastern Canada, and northeastern United States. Biological effects of acidification of fresh waters are detectable below a pH of 6.0. As lake and stream pH levels decreased below pH 6.0, many species of plants, invertebrates, and vertebrates were progressively eliminated. Current research inducates that establishing a maximum permissible value for the volume weighted annual hydrogen ion concentration of precipitation at 25 microeq/liter may protect the most sensitive areas from permanent lake acidification. A PRELIMINARY POLLUTION SURVEY OF THE PAPENKUILS RIVER, PORT ELIZABETH,
Port Elizabeth Univ. (South Africa). Dept. of Zoology.
R. J. Watling, and W. D. Emmerson.
Water SA, Vol 7, No 4, p 211-215, October, 1981. 1 Fig, 3 Tab, 15 Ref.

Descriptors: *Heavy metals, *Water quality, *Water pollution sources, Path of pollutants, Coliforms, Metals, Sediments, Rivers, *Papenkuils River, Port Elizabeth, *South Africa, Nutrients.

Water samples from 20 sites along the course of the Papenkuils River, Port Elizabeth, South Africa, were analyzed for nutrients (ammonia, nitrite, nitrate, phosphate, and total phosphorus), Escherichia coli, and heavy metals. One identified pollution source was the Fishwater Flats sewage works. Many other unknown industries contributed wastes along the entire length of the river (formerly known as Smelly Creek), causing high metal concentrations in water and sediments and an absence of invertebrate fauns. Fecal coliforms were high near the sewage plant discharge and near a stormwater drain. Highest metal levels in water samples were (in micrograms per liter): Cu, 67, Pb, 326, Zn, 3600, Mn, 650; Ni, 106; Cd, 0.88; Cr, 83; and Hg, 1.047. Highest metal levels in sediments were (in micrograms per g): Cu, 740; Pb, 2400; Zn, 22,400; 465; Co, 6.0; Ni, 96; Cd, 15; Cr, 40,000; and Hg, 2. (Cassar-FRC)

AREAWIDE STORMWATER POLLUTION ANALYSIS WITH THE MACROSCOPIC PLANNING (ABMAC) MODEL,
RAMLIT Associates, Berkeley, CA.
Y. J. Litwin, J. A. Lager, and W. G. Smith.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-107947, Price codes: A09 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-223, October 1981. 3 p, 1 Fig. R-806357.

Descriptors: *Storm runoff, *Computer models, *Storm water, *Water pollution, Simulation, Planning, Land use, Water quality, Rainfall-runoff relationships, Nonpoint pollution sources, Wastewater treatment.

A simplified, continuous, stormwater management model (ABMAC) and user's manual were developed to provide an inexpensive, flexible tool for preliminary assessment of stormwater management strategy over large developed and undeveloped areas. The model, intended for use by local engineers and planners, is adaptable for mini-computer applications. The model is designed to simulate runoff, water quality, storage, and treatment while incorporating time and probability into the analysis. It allows for substantial flexibility in terms of input data requirements and output formats. All simulated quantities vary on a daily basis. The model can simulate nonpoint source pollution from a maximum of six land use categories. Six quality constituents are simulated including one user specified constituent. The application and testing of the model in the San Francisco Bay area, from 1976 to 1978, and 1978 to 1980, indicated satisfactory agreement between recorded and simulated records (within 40%). The model can be used effectively in conjunction with more sophisticated models of stromwater runoff and receiving waters. In such applications, ABMAC looks at broad areas and long periods, whereas the more sophisticated models can be best applied to selected, relatively small watersheds. (Moore-SRC)

PARASITES IN SOUTHERN SLUDGES AND DISINFECTION BY STANDARD SLUDGE TREATMENT,

LIBRARY U. OF I.- URBANA-CHAMPAIGN

Tulane Univ., New Orleans, LA. School of Public Health and Tropical Medicine.
R. S. Reimers, M. D. Little, A. J. Englande, D. B. Leftwich, and D. D. Bowman.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-102344, Price codes: A10 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-166, October, 1981. 7 p, 2 Fig, 7 Tab. 805107

Descriptors: *Parasites, *Disinfection, *Sludge, *Protozoa, *Wastewater treatment, Heat, Eggs, Helminths, Lime, Ultrasonics, Seasonal variation, Pathogens, Temperature effects.

Sludge samples collected during each of the four seasons from 27 municipal wastewater plants located in Alabama, Florida, Mississippi, Louisiana, and Texas were examined for thee presence and densities of resistant stages of human and animal parasites. Viable eggs of Ascaris and Toxocara were recovered at least once from every plant and viable eggs of Trichuris vulpis and Trichuris trichiura were recovered at least once from 26 and 15 plants, respectively. Viable eggs of at least 10 other helminths and cysts of a few protozoa were also found in fewer numbers and less frequently. Depending upon the parasite, the inactivation of parasites during sewage treatment fluctuated from season to season, but, in general, most were inactivated in the summer. Laboratory studies verified that destruction of resistant parasite eggs is primarily due to temperature (heat) and not to a speciic digestion process. Very large lime doses were required for the inactivation of viable Ascaris in sludges and results were not always consistent. Laboratory experiments also showed that at certain combinations of ultrasonic frequency intensity and exposure time, Toxocara eggs could be destroyed, but that the same ultrasonic conditions did not affect Ascaris eggs. An important finding of this study is the poor suitability of Ascaris eggs taken from the uteri of gravid female worms as indicators of the characteristics of Ascaris eggs discharged in the feces of the host. (Moore-SRC)

DEVELOPMENT OF THE FECAL STREPTOCOCCUS GROUP AND ITS INDIVIDUAL SPECIES AS WATER QUALITY INDICATORS,
Northern Arizona Univ., Flagstaff. Dept. of Microbiology.
H. K. Speidel.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-211425, Price codes: A02 in paper copy, A01 in microfiche. Report, June, 1981. 13 p. OWRT A-096-ARIZ(1). 14-34-0001-0103.

Descriptors: *Water pollution, *Coliforms, *Bacteria, *Pollutant identification, *Fecal streptococcus, Indicator bacteria, Speciation techniques, Bacterial survival.

Procedures proposed by the U.S. Environmental Protection Agency for the verification and speciation of fecal streptococci were evaluated using 9 standard cultures of streptococci obtained from the American Type Culture Collection (ATCC). The verification portion of the procedure was found to be very useful for the standard cultures as well as environmental isolates. The speciation method was not able to successfully speciate 67% of the standard cultures. The major problems which arose in the use of the speciation scheme included: carbohydrate fermentation reactions, hemolytic reactions, telurite reduction and excessive time and media requirements. A new scheme was developed to speciate the fecal streptococci. Thisnew procedure was based upon differences in the fermentation of six carbohydrates. The new procedure utilizes carbohydrate discs placed on Phenol Red Agar and takes only 24 hours after the verification of the fecal streptococcus isolate. Fecal streptococcal cultures were obtained from a variety of warm-blooded animals from the Northern Arizona Region. The cultures were speciated using the new procedure as well as the EPA procedure. The survival of fecal streptococci in an aquatic system was examined by placing the standard cultures into lake water held at 15 C. Samples were taken at 48 hour intervals and viable counts were made. The survival curves obtained classified the organisms into short term, medium term and long term survivors. The data also indicate that the currently used fecal coliform to fecal streptococcus ratio may not be valid especially after 12 hours from the time the organisms enter the water.

RESPONSES OF NORTHERN NEW ENGLAND LAKES TO ATMOSPHERIC INPUTS OF ACIDS AND HEAVY METALS,
Maine Univ. at Orono. Land and Water Resources Center.
S. A. Norton, R. B. Davis, D. F. Brakke, D. W. Hanson, and K. H. Kenlan.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-211434, Price codes: A06 in paper copy, A01 in microfiche. Report, July, 1981. 90 p, 50 Fig, 6 Tab, 50 Ref, 2 Append. OWRT A-048-ME(1).

Descriptors: *Acid rain, Acidic water, Diatoms, Plankton, *Heavy metals, *Water pollution sources, Cations, Lake sediments, *Lakes, *New England, *Ecological effects.

Ninety-four low-humic lakes in northern New England (82 in Maine) located in largely noncalcareous terrain were studied to detect possible changes in pH and associated effects. Modern colorimetric and electrode pH measurements yield equivalent results plus or minus 0.1 pH unit, permitting comparison of modern electrode pH measurements with older colorimetric measurements. Eight-five percent of the lakes are more acidic now. Studies of present water chemistry indicate that Fe, Mn, Pb, Zn, and Al concentrations tend to be higher with decreasing pH for the set of lakes; Na, K, Ca, Mg, and alkalinity tend to be higher with increasing pH for the set of lakes. Surface sediment chemistry indicates that (at the 95% significance level) the concentrations of Na2O, K2O, MgO, and organics are highest at higher lake pH values; Cu increases with decreasing pH. CaO, FeO, MnO, A12O3, TiO2, Pb, and Zn concentrations do not relate to pH. The relative abundances of taxa of diatom remains in profundal surface sediments from a sub-set of 25 lakes are related to surface water pH's in the range of 4.4 to 7.0. In a cluster analysis, the diatom assemblages from lakes with pH less than 5.7 separate from those with pH greater than 5.8. Greatest taxonomic diversity occurs at pH 5.8. Some unknown factor associated with lake altitude (52 - 1009 m) accounts for scatter in the pH-diatom relationship. In studies of cladoceran associations in profundal surface sediments from 18 of the lakes with a pH range of 4.4 to 6.9, it was not possible to uncouple the effects of pH and altitude (78 - 1123 m). Cladoceran stratigraphy in sediment cores from three high-altitude lakes indicates community changes concurrent with changes in diatom assemblages postulated to be caused by lake acidification.

ESTIMATION OF ACCUMULATION PARAMETERS FOR URBAN RUNOFF QUALITY MODELING,
Geological Survey, Reston, VA.
W. M. Alley, and P. E. Smith.
Water Resources Research, Vol 17, No 6, p 1657-1664, December, 1981. 5 fig, 2 tab, 13 Ref.

Descriptors: *Urban runoff, *Accumulation, *Water quality, *Model studies, Pollutant load, Water pollution sources, Washoff, Fate of pollutants, Runoff, Sensitivity analysis, Paving.

Watershed models use accumulation and washoff equations to simulate the quality of runoff from urban impervious areas. This paper explores methods of estimating accumulation parameters and analyzes the sensitivity of model output to changes in these parameter values. Parameters evaluated are the maximum amount of constituent on effective impervious areas (in kg); the rate constant for constituent removal (per day); and the washoff coefficient (per mm). An equation is given which accounts for observations that the rate of pollutant accumulation is largest for a few days after a rainfall or street cleaning and eventually approaches zero because constituents are resuspended by wind or vehicular traffic. This curve is more general than the linear accumulation curves used in most models. An exponential equation for constituent washoff developed in a previous paper is presented. Results of applying these techniques and sensitivity analysis show that the shape and magnitude of the constituent accumulation curves should be better defined. The amount of residual material remaining on the streets after storms and cleaning must also be considered. (Cassar-FRC)

A FINITE ELEMENT MODEL FOR THE MIGRATION OF LEACHATE FROM A SANITARY LANDFILL IN LONG ISLAND, NEW YORK - PART I: THEORY,
Argonne National Lab., IL.
A. B. Gureghian, D. S. Ward, and R. W. Cleary.
Water Resources Bulletin, Vol 16, No 5, p 900-906, October, 1980. 3 fig, 1 Tab, 31 Ref.

Descriptors: *Leachates, *Model studies, Simulation, Computers, Infiltration, Percolation, Leaching, Soil solution, *Landfills, Sanitary landfills, Waste dumps, Mathematical studies, *Long Island, New York.

This work illustrates the development and accuracy of a two dimensional finite element mathematical model for the migration of ground water contamination. For obtaining a solution to the mass transport equation by means of quadrilateral elements with linear sides, the Upstream (Upwind) FEM seems to be a better choice than the Galerkin FEM to avoid overshoot and oscillations in applying the model to field problems. Due to the fact that the weighting functions are dependent on the cell Courant number, the computational cost will increase slightly if the value of this parameter is other than constant in the progress of the solution. The optimal weighting parameters in the transient simulation need to be precisely defined for grid networks with variable mesh spacing. A field application of the model to the leachate migration from the Babylon sanitary landfill in Long Island, New York, has been carried out. (Baker-FRC)

PROPORTIONS OF SEVERAL ELEMENTS FOUND IN SEWAGE EFFLUENT AND SLUDGE FROM SEVERAL MUNICIPALITIES IN WEST VIRGINIA,
West Virginia Univ., Morgantown. Div. of Animal and Veterinary Sciences.
D. J. Horvath, and R. A. Koshut.
Journal of Environmental Quality, Vol 10, No 4, p 491-497, October/December, 1981. 7 Tab, 30 Ref. A-025-WVA(2).

Descriptors: *Sludge, *Effluents, *Heavy metals, *Wastewater treatment, Metals, Land disposal, Water pollution sources, Cadmium, Zinc, Lead, Nickel, Manganese, Iron, Chromium, Potassium, Magnesium, Phosphorus, Nitrogen, Calcium, Copper, *Municipal wastewater, *West Virginia.

The distribution of 13 elements between sludges and effluents from 11 West Virginia municipal sewage treatment plants was determined from analytical results and the discharge rates. It was obvious that municipalities vary appreciably in their ability to remove elements from wastewater and that the elements vary in behavior. The % of element in effluent followed by % in sludge were Ca, Mg, and K, 82-99, 1-18; Cd, 35-98, 2-65; Cr, 12-86, 9-88; Cu, 15-99, 1-85; Fe, 9-88, 12-91; Mn, 18-81, 19-82; Ni, 30-97, 3-70; Pb, 42-85, 15-58; Zn, 33-84, 16-67; P, 56-96, 4-44; and N, 57-98, 2-43. Ratios of Zn:Cd were 97:1 in influents, 150:1 in sludges, and 30:1 in effluents. Zn:Cu ratios remained about

6:1 through the entire process. This points out cadmium's greater mobility (and the greater environmental threat to water and soil). (Cassar-FRC)

POSSIBLE WATERBORNE TRANSMISSION AND MAINTENANCE OF INFLUENZA VIRUSES IN DOMESTIC DUCKS,
Hong Kong Univ. Dept. of Microbiology.
D. D. Markwell, and K. R. Shortridge.
Applied and Environmental Microbiology, Vol 43, No 1, p 101-116, 1982. 1 Fig, 5 Tab, 25 Ref.

Descriptors: *Water supply, *Diseases, *Contamination, *Ducks, Ponds, Potable water, Public health, *Viruses, Infection, *Influenza, Path of pollutants, Epidemics, Epizootiology, Hong Kong.

The ecology of avian influenza viruses was examined on two duck farms in the Hong Kong area. Monthly examinations were made for a period of 1 year. In one community the predominant virus was H3N2, which is antigenically related to the pandemic Hong Kong strain. The virus was isolated each month from either the feces or the pond water, or both, which suggests a pathway of waterborne transmission. The viruses demonstrated persistence in the community in that 1 and 2 years after the last sampling date viruses of the same antigenic combination were isolated. Infection was asymptomatic. The virus appeared to be dependent on the continual introduction of ducklings susceptible to infection onto virus contaminated water. Ducks 70 to 80 days old were generally free of detectable virus in spite of exposure to virus in pond water. The normal practice of raising ducks of different ages on the same farm and having them share a common water supply seems significant in the large reservoir of influenza viruses in the duck population of southern China. It is conceivable that virus transmission could occur in this manner to other susceptible animals, including humans. (Baker-FRC)

OCCURRENCE AND FATE OF CERTAIN TRIPHENYLMETHANE BLUE DYESTUFFS IN THE AQUATIC ENVIRONMENT,
Thames Water Authority, London (England).
M. L. Richardson, and A. Waggott.
Ecotoxicology and Environmental Safety, Vol 5, No 4, p 424-436, 1981. 3 Fig, 4 Tab, 11 Ref.

Descriptors: *Dyes, *Degradation, Fate of pollutants, *Pollutant identification, Acid Blue 1, Water analysis, Wastewater analysis, Chlorination, Adsorption, Spectrophotometry, Chromatography.

The presence of the triphenylmethane dye, Acid Blue 1 (Chemical Abstracts Services Registry Number 129-17-9) was determined in the aquatic environment by adsorption of XAD-2 ion exchange resin, elution, and spectrophotometric measurement as well as by high performance liquid chromatography. Concentrations of the dye (in micrograms per liter) were 0.6-1.7 in river and reservoir water, 9.2-12.3 in sewage effluent, and less than 0.4 in finished water. Distilled water and tap water containing 2 to 10 micrograms per liter Acid Blue 1 were chlorinated with water containing 2 to 10 micrograms per liter Acid Blue 1 were chlorinated with 1 mg per liter chlorine for 10, 15 or 30 minutes. Dye was destroyed in all but one case; tap water with a 10 microgram per liter concentration of dye exposed for 10 minutes contained 0.6 micrograms per liter residual dye. Exposure of 4 mg per liter dye in distilled water to 15 hours of continuous simulated sunlight did not measurably reduce the dye concentration. (Cassar-FRC)

ACCUMULATION AND DEPURATION OF METALS BY DUCKWEED (LEMNA PERPUSILLA),
Virginia Polytechnic Inst. and State Univ., Blacksburg. Dept. of Biology.
J. R. Clark, J. H. VanHassel, R. B. Nicholson, D. S. Cherry, and J. Cairns, Jr.
Ecotoxicology and Environmental Safety, Vol 5, No 1, p 87-96, 1981. 3 Fig, 1 Tab, 19 Ref.

Descriptors: *Heavy metals, *Aquatic plants, *Bioaccumulation, Fate of pollutants, Metals, Cadmium, Copper, Iron, Manganese, Zinc, Chromium, Lead, Nickel, *Duckweed, Macrophytes, Detention reservoirs, Ash, Powerplants.

Duckweed (Lemna perpusilla) accumulated metals (Cd, Cu, Fe, Mn, Zn, Cr, Pb, and Ni) both in a heavy coal ash secondary retaining basin and under controlled laboratory conditions simulating metal concentrations 0.5, 1, 10, 25, and 100 times the levels of metals found in the retaining basin water. Duckweed in the outdoor basin accumulated Cr, Pb, and Ni to a slightly higher extent and Cd, Cu, Fe, Mn, and Zn to a much greater extent than found in sediments. Levels of metals in the basin water were lower than duckweed and sediment concentrations. During a 14-day depuration period concentrations of Pb, Cr, and Ni declined to sediment levels, Cu and Cd levels approached sediment levels, and Zn, Mn, and Fe levels remained considerably higher. During the 10-day laboratory exposures Pb and Cr bioaccumulation was significantly greater than control at levels of 10 times or greater, and Ni accumulation was significant at the 1 x level and above. Duckweed populations showed high mortality at concentrations 10 x and higher. After 8 days depuration the metal concentrations in duckweed were reduced to control levels. Cu and Cd showed high increases in bioconcentration at the 0.5 and 1 x concentrations and were not eliminated during the depuration period. Duckweed accumulated Zn and Mn at the 1 x exposure and above but did not show depuration. Duckweed's capacity to concentrate metals may result in minimal concentrations of these metals in water during the growing season and sudden releases upon natural die-off in the fall, causing unusually high levels of metals at that time. (Cassar-FRC)

A HYDROLOGIC SIMULATION FOR PREDICTING NONPOINT SOURCE POLLUTION,
Colorado State Univ., Fort Collins. Dept. of Civil Engineering.
K. G. Eggert.
PhD Thesis, 1980. 431 p, 41 Fig, 21 Tab, 117 Ref, 6 Append. University Microfilms International, Ann Arbor, MI; Order No GAX81-10802.

Descriptors: *Hydrologic models, *Water pollution sources, *Watershed management, *Nonpoint pollution sources, Prediction, Mathematical models, Flow channels.

A hydrologic model for use in predicting nonpoint source pollution is developed. The model is a mathematical representation of watershed hydrology and hydraulics. It is formulated to investigate watershed response to management activity. The model simulates water balance on a daily basis by incorporating the processes of evapotranspiration and soil water redistribution resulting from meteorological variations. Surface water runoff is calculated using the kinematic wave approximation for overland and channel flows. The multiple watershed routing component allows large drainage basins to be addressed. Analytic techniques are used for overland flow routing and primary channels, while a numerical solution is used in the main channel segments. Sediment is routed by size fraction using the Meyer-Peter, Muller equation for bedload, and suspended sediment is calculated. Application for validation of individual components is presented. Examples of management alternative impact on water and sediment yields from a hypothetical watershed are also presented. The alternatives examines include clearcut timber harvest by various techniques and the impact of wildland grazing methods. The model's strength are shown to be a flexible computation structure, a minimum of regionally specific code and a representation based on hydrologic and hydraulic processes. The physically based mode allows management alternative changes to be reflected in physically predictable parameters. The model is formulated in such a manner that it may be used to drive other nonpoint source models as required by a specific problem. (Sinha-OEIS)

Descriptors: *Radioactive waste disposal, *Geohydrology, *Test wells, *Hydrologic data, Groundwater movement, Transmissivity, Storage coefficient, Testing procedures, Water sampling, Water analysis, *New Mexico, Eddy County, Waste Isolation Pilot Plant.

Data were collected during hydrologic testing at wells H-4A, H-4B, and H-4C in the southern part of the proposed Waste Isolation Pilot Plant site in southeastern New Mexico. The three water-bearing zones tested, the Magenta and Culebra Dolomite Members of the Rustler Formation and the Rustler Formation-Salado Formation contact, yield water to wells at rates less than 0.9 gallon per minute. Throughout the testing, water-pressure response in the tested zone was monitored by a pressure transducer system. Shut-in and slug tests were conducted to acquire the data from which the following values were derived. Calculated transmissivities for the Magenta, Culebra and the Rustler-Salado contact at wells H-4A, H-4B, and H-4C were 0.06, 0.9, and 0.0006 foot squared per day respectively. Water samples from the Magenta and Culebra had dissolved-solids concentrations of 22,300 and 18,100 milligrams per liter, respectively. The major chemical constituents of ground-water samples from these two zones were sodium, chloride, and sulfate. Water samples from the Rustler-Salado contact had a dissolved-solids concentration of 322,000 milligrams per liter and magnesium, sodium, and chloride were the major constituents. Radium-226, a naturally occurring radioactive element, was present in samples from all three zones. (USGS)

LIBRARY U. OF I. - URBANA CHAMPAIGN

Descriptors: *Organic compounds, *Groundwater, *Aquifers, *Water pollution sources, Organic wastes, Contamination, Wells, Sampling, Water analysis, *New York.

Samples from 56 wells at 49 sites in New York State, excluding Long Island, were analyzed by gas chromatography/mass spectrometry for the presence of organic compounds designated 'priority pollutants' by the U.S. Environmental Protection Agency. Most samples were taken from public-supply wells tapping shallow, permeable aquifers, the most susceptible to contamination. Analytical sensitivity reported by the laboratory for most compounds was less than 1 microgram per liter, but contamination during collection, shipping, or laboratory processing required that concentrations be about 10 micrograms per liter before the presence of a compound could be confirmed. Only a small percentage of wells sampled in this study was found to be contaminated. Where contamination is present, it probably results from point sources such as landfills or dumps rather than from general sources such as atmospheric deposition or proximity to urban centers. Two sites, Brewster in Putnam County and Olean in Cattaraugus County, showed clear evidence of contamination. Two other sites, Corning in Steuben County and Fulton in Oswego County, showed evidence of possible contamination. (USGS)

A CORRELATION STUDY OF BIODEGRADABILITY DETERMINATIONS WITH VARIOUS CHEMICALS IN VARIOUS TESTS II. ADDITIONAL RESULTS AND CONCLUSIONS,
Henkel KGaA, Dusseldorf (Germany, F.R.).
P. Gerike, and W. K. Fischer.
Ecotoxicology and Environmental Safety, Vol 5, No 1, p 45-55, 1981. 3 Tab, 20 Ref.

Descriptors: *Biodegradation, *Organic compounds, *Toxicity, Activated sludge process, Biological treatment, Wastewater treatment, Degradation, *Fate of pollutants, Water pollution effects.

This paper reports work previously started on biodegradability of 44 compounds by 7 tests (the modification of the OECD Confirmatory Test for the application of the carbon analysis, the Zahn-Wellens, the Japanese MITI, the French AFNOR T 90-302, the Sturm, the Modified OECD Screening, and the Closed Bottle Test according to Fischer). This work added two more tests, the U.S. EPA Activated Sludge Test and a model trickling filter. The following conclusions were based on previous and present work. The AFNOR T 90-302 42-day test is a powerful test for noninhibitory compounds and may exaggerate degradation in some cases, e.g., sulfanilic acid. It is overly sensitive toward inhibitory or toxic materials. The EPA activated sludge test strongly exaggerated the predictive value of biodegradability results for the general environment. Environmentally relevant positive results were obtained from the Closed Bottle Tests, the Modified OECD Screening Test, and the MITI Test. The authors feel that special preacclimation procedures should be excluded in the first step of biodegradability testing and that the test duration be limited to 4 weeks. A group of tests was designated appropriate for fail-safe tests of ready biodegradability with the limits 60% dissolved organic carbon removal or 50% BODT or CO2 production. These were the Japanese MITI test, the French AFNOR T 90-302 Test restricted to 4 weeks, the Sturm Test without the preacclimatization step, the Modified OECD Screening Test extended to 4 weeks, and the Closed Bottle Test according to Fischer. ROLE OF NATURAL COLLOIDS IN THE TRANSPORT OF HYDROPHOBIC FOLLUTANTS,
Maryland Univ., College Park. Center for Environmental and Estuarine Studies.
J. C. Means, and R. Wijayaratne.
Science, Vol 215, No 4535, p 968-970, February 19, 1982. 2 Fig, 1 Tab, 12 Footnotes.

Descriptors: *Herbicides, *Adsorption, *Colloids, *Fate of pollutants, Atrazine, Linuron, Estuarine environment, Sorption, Organic matter, Salinity, Hydrogen ion concentration, Chesapeake Bay, *Choptank River, *Patuxent River.

Linear Freundlich adsorption coefficients for the herbicides atrazine and linuron were 1850 and 6750, respectively, in a study of waters containing natural estuarine colloids. Water samples collected from the Choptank and Patuxent Rivers near Chesapeake Bay were filtered to enrich the colloidal fraction. Salinities ranged from 1 to 19 o/oo, and carbon contents of the enriched colloidal fractions from 33.5 to 108.5 mg per liter. The herbicide-colloid-water mixtures were equilibrated in a shaker for 18 hours at 20 C. The sorption constants of atrazine decreased from 2200 to 1800 with a salinity increase from 8 to 16 o/oo. Linuron and atrazine showed sorption peaks at pH 8.0. Significant decreases in sorption were observed as pH decreased to 5.0 or increased to 9.0. The high adsorption coefficients suggest that natural colloids may be important in transporting hydrophobic pollutants in the aquatic environment. (Cassar-FRC)

HEAVY METAL CONTENT IN SEDIMENTS OF LAKES IN SOUTHERN BAVARIA AS A SIGN OF LONG-TERM ENVIRONMENTAL IMPACT (SCHWERMETALLGEHALTE IN SEDIMENTEN SUDBAYERISCHER SEEN ALS INDIKATOREN LANGFRISTIGER UMWELTBELASTUNG),
Munich Univ. (Germany, F.R.). Geographisches Inst.
G. Michler, C. Steinberg, and P. Schramel.
Wasserwirtschaft, Vol 71, No 11, p 323-330, 1981. 4 Fig, 3 Tab, 27 Ref. English Summary.

Descriptors: *Heavy metals, *Lakes, *Sediments, *Bavaria, Germany, Cores, Dating, Limnology, Path of pollutants, History, Isar River, Diversion, Catchment areas, Municipal wastes.

Typical examples of results obtained to date in a study of the heavy metal contents in sediment cores from 18 South Bavarian lakes are presented. The Ammersee core was studied for vertical distribution of heavy metals. The heavy metal contents in the lower layer were taken as the geological background. The heavy metal contents generally increased at an accelerating rate, over time, with some irregularities which could be correlated with historical events and with a decrease in the last 10-20 years corresponding to decreased coal burning. According to the geoaccumulation index, the Ammersee is classified as moderately to heavily loaded with cadmium, heavily loaded with zinc, and scarcely loaded with copper, lead and chromium. The Walchensee illustrates the effects of water use projects on heavy metal levels. Part of the upper Isar and Rissbach flows were diverted into the Walchensee in 1924 and 1949 to provide increased flows for a hydroelectric plant, increasing the catchment area of the Walchensee from 74 sq km to 770 sq km. The metal components could be divided into two groups: those which are deposited at practically constant rates in the absence of increased sedimentation due to water projects, and those whose levels increased continuously even after the construction erosion ended. Copper accumulation is showing a continuous increase accompanying introduction of treated wastewaters into the Isar. The Speichersee is an artificial lake, receiving large volumes of wastewater, from Munich. Even considering its function as a 'heavy metal trap' the concentrations found were alarming. Lead concentrations exceeding 2000 ppm and cadmium concentrations exceeding 100 ppm were found. (Carroll-FRC)

DEVELOPMENT OF IMPROVED STORMWATER QUALITY MODELS,
Union Coll., Schenectady, NY. Dept. of Civil Engineering.
T. K. Jewell, and D. D. Adrian.
Journal of the Environmental Engineering Division, Proceedings of the American Society of Civil Engineers, Vol 107, No 5, p 957-974, October, 1981. 6 Tab, 16 Ref. OWRT A-095-MASS, B-059-MASS.

Descriptors: *Urban hydrology, *Storm water, *Water quality, Rainfall-runoff relationships, Model studies, Water pollution sources, *Fate of pollutants, Runoff, *Urban runoff.

A method for developing urban storm water pollutant washoff models has been outlined for the purpose of improving reliability of results. The procedure consists of testing several linear and linear transform multiple regression models for estimating pollutant washoff loadings as a function of storm and basin characteristics using measured data. Then the best model can be chosen for each pollutant using the coefficient of determination and othe criteria. Although estimates of buildup and washoff are eliminated, it is still necessary to gather storm event data for each basin to be modeled. The method is illustrated using data from Seattle, Washington, to predict storm event total loadings for long-term simulation purposes. Calculated results were as follows: suspended solids and COD, within the range of reported values; ammonia, slightly less than reported values. (Cassar-FRC)

NEARFIELD PERFORMANCE OF RIVER DIFFUSERS,
Kansas Univ., Lawrence. Dept. of Civil Engineering.
A. D. Parr, and J. G. Melville.
Journal of the Environmental Engineering Division, Proceedings of the American Society of Civil Engineers, Vol 107, No EE5, p 995-1008, October, 1981. 9 Fig, 1 Tab, 10 Ref. OWRT A-077-ALA.

Descriptors: *Diffusers, *Thermal pollution, *Mixing, Rivers, Model studies, Mathematical models, Mississippi River, Powerplants, Heated water, Thermal water, Fate of pollutants, Temperature, Water temperature, Flow characteristics.

A model was developed to describe the flow field induced by a submerged multiport diffuser discharging in a rectangular channel. Nearfield dilution was determined as a function of effluent and ambient flow parameters. A family of curves is given for a range of conditions characteristic of prototype river diffusers (centered and shore-attached). Comparisons of model predictions with data observed in the Mississippi River downstream from the Quad Cities Nuclear Power Station diffuser were generally in agreement. However, the depth-averaged minimum dilution was underpredicted by about 7%, probably as a result of neglecting lateral entrainment. (Cassar-FRC)

ORGANIC CARBON FLOW IN A SWAMP-STREAM ECOSYSTEM,
North Carolina Univ. at Chapel Hill. Dept. of Environmental Sciences and Engineering.
P. J. Mulholland.
Ecological Monographs, Vol 51, No 3, p 307-322, September, 1981. 9 Fig, 6 Tab, 72 Ref. OWRT B-084-NC, B-110-NC.

Descriptors: *Organic carbon, *Litter, *Streams, *Swamps, *Organic loading, *North Carolina, Total organic carbon, Carbon, Decomposing organic matter, Organic matter, Respiration, Detritus, Dissolved solids, Ecosystems, Oxidation, Watersheds, Wetlands, Productivity.

An annual organic carbon budget for a section of Creeping Swamp, North Carolina is presented. Most of the input was allochthonous, with high autochthonous organic carbon input from filamentous algae during February and March. The output of organic carbon by fluvial processes was 36% of total annual inputs, indicating that the swamp section studied was 64% efficient at retaining organic

carbon. Most organic carbon was retained by respiration. Indices of organic matter processing and a loading potential index were used to compare organic carbon dynamics in the Creeping Swamp segment to that of upland stream segments. The organic carbon loading potential of the swamp was greater than that of the comparison streams, due to its great width and complete canopy. The dense vegetation and low gradient of the swamp increase organic carbon retention by maintaining low water velocities with little erosive force, tortuous flow paths and debris dams. Retention and oxidation of organic carbon in the flooded Creeping Swamp ecosystem occurs in the floodplain. A net annual export of organic carbon in the dissolved form is attributed to the extensive drainage network of the swamp stream system. (Geiger-FRC)

SOME EFFECTS OF LAND USE ON BACTERIOLOGICAL WATER QUALITY IN A RECREATIONAL LAKE,
Ontario Ministry of the Environment, Rexdale.
G. S. Hendry, and A. Troth.
Water Research, Vol 16, No 1, p 105-112, January, 1982. 9 Tab, 26 Ref.

Descriptors: *Bacterial analysis, *Land use, *Lake shores, *Water pollution sources, Fate of pollutants, Water quality, Coliforms, Lakes, *Mississippi Lake, *Ontario, Heterotrophic bacteria, Swimming, Eutrophic lakes, Recreation, Chlorophyll a, Diseases, Water pollution effects, Public health.

A bacterial analysis of water samples from Mississippi Lake, a shallow eutrophic lake in Ontario, indicated that the main sources of fecal coliforms were cattle watering sites, farms, public beaches, flooded and substandard septic tanks, and a bird sanctuary. Sampling was done May 28-June 6 and July 20-29, 1976, at 75 shoreline locations, 5 mid-lake stations and 5 lake bottom locations. Water quality impairment was localized near the suspected pollution sources. After a rain, levels of fecal coliforms and fecal streptococci increased 10-fold in the lake surface water. Bacterial counts returned to previous levels after 2-3 days. Aerobic heterotrophic bacterial counts at mid lake surface sites were 1600 per 100 ml in June and 8270 per ml in July. Average chlorophyll a concentrations were 2.0 micrograms per liter. A survey of cottage residents on the lake indicated that 57 of 67 reported infections were ear infections, which were experienced by3.28% of bathers. Ear infections were more common in the bathers who spent more time in the water. Young people had higher ear infection rates than adults. Suggestions to improve the water quality of this lake are: eliminate cattle watering sites from the lake shore, correct substandard septic tanks, and open more public beaches. (Cassar-FRC)

ATTENUATION OF POLYBROMINATED BIPHENYLS AND HEXACHLOROBENZENE BY EARTH MATERIALS,
Municipal Environmental Research Lab., Cincinnati, OH.
N. M. Lewis.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-107558, Price codes: A04 in paper copy, A01 in microfiche. EPA-600/S2-81-191, December, 1981. 7 p, 2 Fig, 6 Tab. R-804684-01.

Descriptors: *Polybrominated biphenyls, *Hexachlorobenzene, *Leaching, *Solubility, *Land disposal, Waste disposal, Leachates, Microbial degradation, Pollutants, Adsorption, Soil contamination, Landfills, Water pollution sources.

This laboratory study of the aqueous solubility, adsorption, mobility, and microbial degradation of polybrominated biphenyls (PBB's) and hexachlorobenzene (HCB) was undertaken to provide information on their behavior in the environment, particularly on the potential for their movement through soil at land disposal facilities for hazardous wastes. PBB's were more than 200 times, and HCB more than 2.5 times more soluble in landfill leachate than in distilled water. Also the solubilities of PBB's and HCB were higher in creekwater and landfill leachates than in purified waters; this was correlated with the level of dissolved organics in the waters. HCB showed a greater tendency for adsorption on soils than did PBB's. There was a high direct correlation between the total organic carbon content of the soils and the amount adsorbed. PBB's and HCB were strongly adsorbed by carbonaceous Ambersorb XE-348 from organic solvents. PBB's and HCB remained immobile in earth materials when leached with water and DuPage leachate, but were highly mobile when leached with organic solvents. PBB's and HCB were found to be resistant to microbial degradation. It is recommended that disposal of PBB or HCB wastes dissolved in organic solvents, or co-disposal of PBB or HCB materials with organic solvents be avoided at land disposal sites unless a carbonaceous liner material is used. Descriptors: *Mathematical models, *Computer models, Highways, *Runoff, *Water pollution sources, Storm runoff, *Highway effects, Environmental effects, Urban runoff, Rainfall-runoff relationships.

The purpose of the predictive procedure is to provide highway designers with a simplified tool to estimate the quantity and quality of storm generated highway runoff. The predictive procedure is comprised of a series of equations which can be computerized to form a mathematical model. The procedure is made up of four components correspondng to the following functions: rainfall runoff; pollutant buildup; pollutant wash-off; and constituent loadings. The predictive procedure can be used for Environmental Impact Statements or to determine the loadings for analysis of the pollutant discharge effect of various design storms at a particular site. The procedure can also be used to evaluate existing highway systems. Equations were developed relating runoff volume to rainfall volume for three highway site types: urban elevated bridge decks with 100% paved areas; urban paved and nonpaved drainage areas; and rural flush shouldered highways. Total solids showed the highest correlation with other monitored parameters and is therefore used as the carrier pollutant in the predictive procedure to estimate 16 other parameters. The wash-off coefficients developed for the three highway site types used in this study are: 5.0 for urban elevated bridge decks; 6.5 for urban paved and nonpaved drainage areas; and 12.0 for rural flush shouldered highways. Descriptors: *Highways, *Runoff, *Water pollution sources, *Computer programs, Snowmelt, Storm runoff, *Water quality, Hyetographs, Hydrographs, Rainfall-runoff relationships, Path of pollutants.

The Data Storage Program (DSP) was developed as part of a project to determine the characteristics of highway runoff. Due to the nature of the study, an extensive data collection and chemical analysis program was required and more than 14,000 pieces of data were generated. DSP was developed to: retain a large quantity of field generated data in an organized and easily accessible format; permit conversion of standard units to metric; and provide a mechanism by which the data can be recalled for optional plotting or statistical analysis. The data base developed during the project is perhaps the most extensive highway runoff quantity/quality data in existence. This data is available on magnetic tape with access provided by DSP. Highway runoff is highly variable in that it results primarily from precipitation or snowmelts and as such its description contains a rainfall hyetograph, a runoff hydrograph, water quality parameters, dustfall data, and various site characteristics. The program provides a readily available and convenient means for storage and analysis of environmental and operational data collected during future highway runoff studies. (Moore-SRC)

Descriptors: *Highways, *Runoff, *Water pollution sources, *Storm runoff, *Highway effects, Environmental effects, Rainfall-runoff relationships, Nutrients, Heavy metals, Particulate matter, Oxygen demand, Coliforms, Oil pollution, Fate of pollutants.

From the Spring of 1976 to September 1977, a total of 159 storm events were monitored at six sites: three sites in Milwaukee, Wisconsin; one in Harrisburg, Pennsylvania; one in Nashville, Tennessee; and one in Denver, Colorado. The data were evaluated for: rainfall/runoff relationships; highway runoff pollutant loadings and variations with time; differences in pollutant characteristics from paved and non-paved areas; and correlation of pollutants among measured parameters as well as with highway operation related factors. The average runoff volume to rainfall volume coefficients for non-winter storm events were found to vary between 0.20 to 0.92. Most heavy metals were associated with the particulate matter in highway runoff. The average BOD5 values in highway runoff were found to be comparable with effluent from a well

LIBRARY U. OF I.- URBANA CHAMPAIGN

operated secondary municipal treatment plant. The nutrient loadings were generally comparable to urban stormwater runoff. Sizable concentrations of total coliforms, fecal coliforms, and fecal streptococci were found at all sites. The average oil and grease concentrations in monitored storm events ranged between 1 mg/l at the all-grassy site to 20 mg/l at the all-paved site. Generally, the all-paved site showed the highest loadings for various constituents. (Moore-SRC)

Internale Revue der Gesamten Hydrobiologie, Vol 66, No 2, p 223-248, 1981. 12 Fig, 4 Tab, 38 Ref. English summary.

Descriptors: *Plankton, *Eutrophication, *Marine bacteria, Marine algal, Nutrients, Euphotic zone, Dissolved organic matter, Metabolism, *Carbohydrates, Phytoplankton.

Relationships between heterotrophic activity and phytoplankton excretion were studied in naturally and artificially eutrophicated systems. Excretion appears to have a greater significance in zones of low phytoplankton content than of high content. It increases in the presence of light and ammonium ion. Ion exchange resin analysis of the excreta indicated that the acid fraction generally dominates, while the neutral (glycid) fraction is more significant under dim light conditions. Two enrichment studies on eutrophic and oligotrophic marine waters. In the first case heterotrophy increases with algal biomass; in the second case a first heterotrophic optimum precedes the exponential growth phase of the algae and a second optimum follows. The findings aid in explaining the observed variations in degradation of organic matter depending on the phytoplankton composition. The metabolic adaptability of the bacterioplankton appears responsible for their ability to thrive in nutrient-poor water. In upwelling zones the bacterioplankton activity determines the chemical composition of the water. It also contributes to the maintenance of low dissolved organic carbon contents across large gradients of primary productivity in the photic zone. (Carroll-FRC)

DISPERSION COEFFICIENTS IN ESTUARIES,
Birmingham Univ. (England).
J. R. West, and T. W. Broyd.
Proceedings of the Institution of Civil Engineers, Part 2: Research and Theory, Vol 71, No 3, p 721-737, September, 1981. 7 Fig, 3 Tab, 27 Ref.

Descriptors: *Saline water intrusion, *Solute transport, *Mixing, *Dispersion coefficients, Tidal hydraulics, Fate of pollutants, *Estuaries, Tidal effects.

Published methods of predicting longitudinal dispersion coefficients for estuaries were compared using field data from five British estuaries, Mersey, Conwy, Tay, Usk, and Thames. Values of dispersion coefficients predicted by theoretically based expressions gave values within a factor of three of the gross field data values for mean tidal range and low river flow in all five estuaries. In the narrow, shallow estuaries the transverse oscillating shear mechanisms were dominant. Transverse gravitational shear mechanisms dominated in the wide estuaries. An empirical expression predicted tidal mixing within a factor of five of the field data values. The theoretical and empirical expressions can provide useful estimates of dispersion coefficients if carefully used. (Cassar-FRC)

SELECTED TRACE METALS IN THE UPPER ST. JOHNS RIVER AND THEIR LAND USE RELATIONSHIPS,
General Battery Corp., Reading, PA.
J. A. Leed, and T. V. Belanger.
Florida Scientist, Vol 44, No 3, p 136-150, 1981. 8 Fig, 5 Tab, 14 Ref.

Descriptors: *Rivers, *Trace metals, *St Johns River, Florida, Land use, Path of pollutants, Water pollution sources, Copper, Zinc, Iron, Environmental effects, Water analysis, Fish, Sediments.

In this study iron, copper and zinc were monitored in four species of fish, in the water and in sediments of the upper St. Johns River in order to evaluate land use-water quality relationships. The role of natural interacting processes was also investigated in regulating surface water trace metal concentrations, the accumulation of trace metals in bottom sediments and fish tissues, the relationships between fish weight or total length and trace metal levels in the muscle, gills, and liver, and the relationship between volatile solids (organic matter) and trace metal concentrations in the sediments. Total copper and zinc were present at low concentrations in the surface waters of the upper St. Johns River, but total iron frequently occurred at concentrations exceeding the state standard of 300 micrograms/liter. Levels of total iron appear to be regulated by resuspension of bottom sediments caused by increased discharge and resulting turbulence. Groundwater inputs may influence trace metal content, particularly of iron. The average surface water total iron was highest in the headwaters region of the river above Lake Helen Blazes, decreasing in a northward direction to Lake Washington, and increasing to Lake Poinsett. Higher levels of iron, copper and zinc were found in sediments containing higher percentages of organic matter. Analysis of these metals in the tissues of fish indicates that they are concentrated in the liver, with lower amounts in the gill and muscle tissue. Total copper and total zinc were highly correlated to land use associated with urban activities. (Baker-FRC)

INFLUENCE OF AN AMERICIUM SOLID PHASE ON AMERICIUM CONCENTRATIONS IN SOLUTIONS,
Battelle Pacific Northwest Labs., Richland, WA.
D. Rai, R. G. Strickert, D. A. Moore, and R. J. Serne.
Geochimica et Cosmochimica Acta, Vol 45, No 11, p 2257-2265, November, 1981. 5 Fig, 3 Tab, 30 Ref.

Descriptors: *Americium, *Solubility, *Radioactive waste disposal, Waste disposal, Fate of pollutants, Equilibrium, Hydrogen ion concentration, Minerals, Sorption, Chemical precipitation, Solute transport, *Groundwater pollution.

Solubility mechanisms of americium, a long-lived waste product of nuclear energy production, were studied to predict Am concentrations in groundwaters. Suspensions of sediments contaminated with acidic (pH 2.5) liquid radioactive wastes were equilibrated in 0.0015 M CaCl2 solutions adjusted with NaOH to pH of 4.35, 5.3, 6.8, and 7.72 for 100 days. The solubility-limited Am concentrations decreased 10-fold with one unit increase in pH. An equation is presented for predicting Am concentrations in solutions containing contaminated sediments from old waste disposal sites. It is not applicable to high carbonate groundwaters. Lithospheric materials such as granite, basalt, tuff, and salt generally contain alkaline groundwater, and therefore Am is not expected to be very mobile in this environment. The chemical form of Am in aqueous solution is probably Am(OH)2+; the form in soil was not determined, but is probably not Am(OH)3. Published data on sorption coefficients of Am by different rocks, soils, and minerals were evaluated. Final Am solution concentrations calculated from sorption coefficients of earth materials with solutions agreed well with concentrations predicted from the solubility of solid Am in soil. This indicates that sorption coefficient data are controlled by Am precipitation. (Cassar-FRC)

GROUND WATER MONITORING OF UNDERGROUND COAL MINES,
Moody and Associates Inc., Meadville, PA.
B. A. Waite.
Mining Engineering, Vol 34, No 2, p 170-171, February, 1982.

Descriptors: *Monitoring, *Groundwater movement, *Coal mining, Mining engineering, *Regulations, Dewatering, Drainage effects, Observation wells, Wells.

The coal mining industry has been concerned about the new regulations requiring groundwater monitoring of underground mines. A study of 30 monitoring plans for existing mines in Pennsylvania, West Virginia, and Ohio indicates that for deep mines ranging from 20-81 sq km, 5 to 20 monitoring wells will be required. Variables to consider in electing monitoring locations are aerial coverage of the mine, topographic and structural settings, position of the aquifer in relation to coal seams, population densities, and mining status of various sections of the mine. Possible problems caused by installing monitoring wells include caveins, undesirable dewatering, and disruption of mining plans. Methods for minimizing adverse effects on groundwater are sealing mining openings on completion of mining, providing additional roof supports in wet areas, and avoiding excessively fractured zones. Mine operators face difficulties in collecting data and in being responsible for groundwater supply and quality. For example, considerable money and time may be expended trying to substantiate or refute lost water claims. Future development in a dewatered area may force the coal company to provide a water supply for home owners and industry. It may be difficult or impossible to obtain permission to enter private property and adjacent coal mines to obtain data as required for regulatory compliance. (Cassar-FRC)

5C. Effects Of Pollution

METABOLIC RESPONSES OF AQUATIC BACTERIAL POPULATIONS TO SELECTED INSECTICIDES,
Texas Univ. Health Science Center at Houston. School of Public Health.
H. E. Murray, and R. K. Guthrie.
Water Resources Bulletin, Vol 16, No 4, p 749-751, August, 1980. 3 Fig, 9 Ref.

Descriptors: *Bacteria, *Insecticides, *Oxygen uptake, Water pollution effects, Biodegradation, Metabolism, Malathion, Sevin, 1-Naphthol, Aquatic bacteria, Warburg respirometry, Lake Houston samples, Laboratory tests, Aquariums.

Bacterial populations from Lake Houston were exposed in laboratory aquariums to 5 mg per liter concentrations of sevin or malathion at temperatures of 23, 28, and 33 C. Predominant genera were Pseudomonas, Alcaligenes, Flavobacterium, Bacillus, and Enterobacter. Increased uptake of oxygen as measured by Warburg manometry indicated degradation of sevin by the bacteria. Addition of 1-naphthol, the principal degradation product of sevin, produced the same stimulation of bacterial growth. Plate counts were higher for 3-5 days following sevin or 1-naphthol addition and returned to normal after 10-14 days. Addition of malathion or malathion monocarboxylic acid did not affect metabolic rates at any temperature. However, at 33 C a slight inhibition in bacterial growth was noted. Bacterial counts rose when malathion was reapplied to the aquariums after 2 weeks, possibly indicating a selection of genera able to metabolize the chemical. (Cassar-FRC)

EFFECTS OF PHENOL ON OXYGEN CONSUMPTION IN THE WHELK, BULLIA DIGITALIS (DILLWYN),
Cape Town Univ., Rondebosch (South Africa). Dept. of Zoology.
T. Golombick, and A. C. Brown.
South African Journal of Science, Vol 76, No 8, p 375, August, 1980. 16 Ref.

Descriptors: *Phenols, *Shellfish, *Toxicity, Oxygen demand, *Sea water, Control waters, Effluents, Industrial wastes, *South Africa, Water pollution effect.

High concentrations of pheolic compounds were found from an industrial effluent discharging into the sea on the west coast of south Africa near Cape Twon. To assess potential effect of the discharge, oxygen consumption in large female whelks (Bullia digitalis) was measured after exposure to phenol in natural sea water at 15 deg C. Animals exposed to 0.1% phenol for five minutes died after returning to sea water. Those exposed to 0.005% phenol all recovered although stress symptoms were noted. At 0.1% phenol, oxygen uptake showed an immediate sharp decrease and fell to about 1/5 the control level. At 0.005% phenol, oxygen uptake increased to double the control value. thus, high concentrations caused a decrease and low concentrations caused an increase. These results are consistent with results found by other researchers with other invertebrates. (Small-FRC)

APPLICATION OF THE OECD EUTROPHICATION MODELING APPROACH TO LAKE RAY HUBBARD, TEXAS,
Brown and Caldwell, Sacramento, CA.
E. M. Archibald, and G. F. Lee.
Journal of the American Water Works Association, Vol 73, No 11, p 590-599, November, 1981. 13 Fig, 2 Tab, 14 Ref.

Descriptors: *Lakes, *Eutrophication, *Phosphorus, *Lake Ray Hubbard, *Texas, Dallas, Water quality, Reservoirs, Water pollution effects, Dissolved oxygen, Oxygen, Taste, Odor, Model studies, Algae, Nutrients, Chlorophyll a, *Water pollution control.

Lake Ray Hubbard, Texas, used for drinking water and recreation by the Dallas Water Utilities, was the site of algal-related taste and odor problems during the mid-1970's. The lake, of area 550 million cu m and average depth 6.3 m, is divided into four areas, the Main Body and three arms. Extensive water quality sampling and application of the Organization for Economic Cooperation and Development eutrophication models showed that low flows from the Lake Lavon arm into the Main Body increased the average chlorophyll a levels from 6.5 to 11.5 micrograms per liter for 1976-77 data. The models predicted that an 85% reduction in phosphorus in domestic wastewater discharged into the lake would significantly improve water quality. However, it is unlikely that the P load can be sufficiently reduced to maintain oxygen in the hypolimnion during the thermal stratification period unless period unless both point and nonpoint pollution sources are strickly controlled. Increased population in the watershed will aggravate the problems of disagreeable tastes and odors, shortened filter runs, and trihalomethane formation. (Cassar-FRC)

DIEL VARIATION IN THE ABUNDANCE, VERTICAL DISTRIBUTION, AND SPECIES COMPOSITION OF PHYTOPLANKTON IN A EUTROPHIC ENGLISH LAKE,
Freshwater Biological Association, Ambleside (England).
E. Frempong.
Journal of Ecology, Vol 69, No 3, p 919-939, 1981. 7 Fig, 2 Tab, 58 Ref.

Descriptors: *Eutrophication, *Phytoplankton, *Lakes, *England, Vertical distribution, Seasonal variation, Stratification, Thermal stratification.

The diel distribution of chlorophyll and component species throughout the water column in a productive English lake over a range of seasonal phases is discussed. Esthwaite Water is the lake, with an area of about 1 square kilometer, a mean depth of 6.4 meters, and a maximum depth of about 15.5 meters. The lake is composed of three basins. About 83% of the total lake volume is within the 8 meter depth isobath. Eight sampling periods were arranged between June 1977 and September 1978. The seasonal variation of environmental factors, such as thermal and density stratification, largely controlled the size of the diel variations in biomass concentrations. Under strongly stratified conditions and with little turbulence the amplitude of the diel variations increased, and the influence of many factors was restricted to the upper water layers. High daytime light flux influenced the distribution of the dominant motile algae. Sub-surface population maxima under high surface light flux were also noted for two buoyant species, Anabaena flos-aquae and A. solitaria. Loss or accumulation of phytoplankton at the sampling site by lateral transport was associated with wind-induced water movements. Two flagellates, Ceratium hirundinella and Cryptomonas ovata, showed diel vertical migration. Pseudo-diel variations were recognized and linked to weather events with some degree of regularity. RESPONSES OF BACTERIA TO THE PRESENCE OF CARBARYL IN WATER. II. PURE CULTURE VS. MIXED CULTURE RESPONSE,
Texas Univ. at Austin. School of Public Health.
R. K. Guthrie, U. A. Anugwelem, and E. M. Davis.
Water Resources Bulletin, Vol 17, No 6, p 1005-1007, December, 1981. 1 Fig, 1 Tab, 6 Ref.

Descriptors: *Bacterial analysis, *Indicators, *Carbaryl, *Pollutant identification, Pathogens, Bioindicators, Microbiological studies, Insecticides, Coliforms, Escherichia coli, Streptococcus faecalis, Salmonella typhimurium, Staphylococcus aureus, Water pollution effects.

The effects of 1 or 5 mg per liter carbaryl in water on bacteria were studied on pure and mixed cultures. Bacteria were the indicators, Escherichia coli, and Streptococcus faecalis, and the pathogens, Salmonella typhimurium and Staphylococcus aureus. Oxygen uptake was inhibited by 5 mg per liter carbaryl in all pure cultures. E. coli and . typhimurium pure cultures showed increased oxygen uptake in 1 mg per liter carbaryl. Mixtures of all 4 bacteria showed no increase in oxygen uptake. Carbaryl at 1 and 5 mg per liter significantly inhibited oxygen uptake for mixtures of E. coli-S. faecalis and E. coli-S. aureus, significantly increased oxygen uptake for E. coli-S. typhimurium, and insignificantly increased oxygen uptake for S. typhimurium-S. aureus. Carbaryl had no effect on S. typhimurium-S. faecalis mixtures. Survival times in 5 mg per liter carbaryl were > 8 days for pure and mixed cultures of E. coli, pure cultures of S. faecalis, and mixed cultures of S. typhimurium; < 8 days for pure and mixed cultures of S. aureus, mixed cultures of S. faecalis, and pure S. typhimurium. In mixed cultures in the presence of carbaryl the one pathogen (S. typhimurium) had increased survival time and one indicator (S. faecalis) had reduced survival time. This would make S. faecalis unsuitable as an indicator of fecal pollution under these conditions. (Cassar-FRC)

RESPONSE OF BACTERIA TO THE PRESENCE OF CARBARYL IN WATER. I. RESPONSE OF BACTERIAL INDICATORS VS. RESPONSE OF PATHOGENIC BACTERIAL SPECIES,
Ife Univ. (Nigeria). Dept. of Environmental Health.
U. A. Anugwelem, R. K. Guthrie, and E. M. Davis.
Water Resources Bulletin, Vol 17, No 6, p 1000-1004, December, 1981. 3 Fig, 9 Ref.

Descriptors: *Bacterial analysis, *Indicators, *Carbaryl, *Pollutant identification, Pathogens, Bioindicators, Microbiological studies, Insecticides, Coliforms, Escherichia coli, Streptococcus faecalis, Salmonella typhimurium, Staphylococcus aureus, Water pollution effects.

The effects of 1 or 5 mg per liter carbaryl in water on fecal pollution indicators (Escherichia coli and Streptococcus faecalis) and the pathogens (Salmonella typhimurium and Staphylococcus aureus) were determined by plate counts and Warburg respirometry. Growth of gram negative bateria, E. coli and S. typhimurium, were initially stimulated by carbaryl, whereas gram positive bacteria, S. faecalis and S. aureus, were inhibited. Over the 8 day study all bacteria died off more rapidly in the presence of carbaryl. Small concentrations of carbaryl can lead to incorrect conclusions in bacterial analysis of water. In some cases indicators died off before pathogens, contrary to the requirements for an indicator bacteria. The ratio of fecal coli to fecal streptococci would lead to false impressions during the period of initial growth stimulation. (Cassar-FRC)

WHEN A WATER SUPPLY WENT BAD,
American City and County, Vol 96, No 12, p 33, 35-36, December, 1981.

Descriptors: *Municipal water, *Chemical wastes, *Activated carbon, *Water pollution effects, *Water treatment, Adsorption, Trichloroethylene, Water supply, Rockaway, *New Jersey, Organic compounds, Political aspects.

Two New Jersey communities, Rockaway Borough and Rockaway Township, handled toxic organic chemical pollution of their water supplies by installing activated carbon water treatment systems. Testing of municipal well water showed trichloroethylene levels as high as 554 ppb in borough water and 180 ppb in township water. The township water was also contaminated with diisopropyl ether and methylene chloride, gasoline additives leaking from a gas station storage tank. Potable water was supplied to residents from water trucks until the activated carbon treatment systems were placed in operation, 21 days for the township and about 6 weeks for the borough. Although sources of chemicals were identified and corrective measures taken, high levels of organic chemicals remained in the well water. However, the carbon adsorption systems removed the contaminants to below the 1 ppb detection limit. (Cassar-FRC)

COMBINED EFFECTS OF CADMIUM AND ZINC ON A LAKE MICHIGAN ZOOPLANKTON COMMUNITY,
Argonne National Lab., IL.
J. S. Marshall, D. L. Mellinger, and J. I. Parker.
Journal of Great Lakes Research, Vol 7, No 3, p 215-223, 1981. 2 Fig, 4 Tab, 37 Ref.

Descriptors: *Cadmium, *Zinc, *Toxicity, *Zoopankton, Metals, Heavy metals, Crustaceans, Lakes, *Lake Michigan, *Green Bay, *Water pollution effects, Population density, Dissolved oxygen, Species diversity, Species composition.

The effects of cadmium and zinc alone and in combination on the zooplankton community of Green Bay, Lake Michigan, were studied in situ during duplicate 3-week experiments conducted in

LIBRARY U. OF I.- URBANA CHAMPAIGN

8 liter plastic carboys suspended in the epilimnion. Metal treatments (all in micrograms per liter) were: (1) Cd, 2; (2) Zn, 100; (3) Cd, 2, plus Zn, 100, and (4) Cd, 1 plus Zn, 50. Cd109 and Zn 65 were used as tracers to determine the sorption of Cd, and Zn by the different particle size fractions. All four treatments significantly reduced total crustacean density, species diversity, community similarity indexes, and final dissolved oxygen concentrations during the August 1-22, 1978, run. Average crustacean densities for the treatments were: control, 68 plus or minus 11.9, (1) 46.1 plus or minus 15.4, (2) 21.9 plus or minus 6.0, (3) 17.3 plus or minus 1.4, and (4) 30.8 plus or minus 6.4. The effects of treatment (3) were similar to those of 100 micrograms Zn per liter alone since Cd uptake by zooplankton was reduced by the Zn. Results suggest that less than a ten-fold increase in Zn levels in the lake (from the present 5 micrograms per liter) would have pronounced effects on the plankton community. (Cassar-FRC)

THE EFFECTS OF SEDIMENTATION ON AQUATIC LIFE OF THE KANKAKEE RIVER, PHASE II: QUANTITATIVE STUDIES AND THREATENED, ENDANGERED, AND RARE SPECIES,
Illinois Natural History Survey, Chicago.
A. R. Brigham, L. B. Suloway, and L. M. Page.
Document No. 81/37 November 1981. Illinois Department of Energy and Natural Resources, Chicago. 16 p, 5 Fig, 8 Tab, 24 Ref.

Descriptors: *Sedimentation, *Substrates, Sediments, Sand, Silt, *River flow, Biological samples, Biomass, Benthic flora, Benthic fauna, Macroinvertebrates, Rivers, Mussels, Fish, Fish populations, *Ecological effects, *Aquatic life, *Kankakee River, Illinois.

Increased sediment transport is considered the most serious water pollution problem in Illinois. Of concern is that when sediments washed into the Kankakee in Indian reach the slower-moving Illinois portion of the river, diversity and abundance of aquatic life are reduced. The objectives of this study were to assess the impact in Illinois of upstream activities that might increase sediment transport, especially upstream of Kankakee, by quantitatively estimating principal macroinvertebrate populations associated with known substrate types, and to combine this sampling with other sampling to assess the status of endangered or threatened species. In 1979, 44 species of fish were collected. Sites where sand or silt-sand substrates predominated supported fewer species, fewer individuals, and lower biomass than sites with coarser substrates. The transition area had about the same number of species and biomass but fewer individuals as sites where coarser substrates predominated. Thireeen species of mussels were collected. Predominantly sand substrates support few, if any, mussels. Density and number of species were varied at sites with substrates other than predominantly sand. Sedimentation of the non-sand areas would destroy part of the mussel fauna. Also in 1979, 143 taxa of benthic macroinvertebrates were collected. Sites with progressively more complex substrates supported more taxa. Sites where sand or sand-silt substrates predominated supported fewer taxa than sites with substrates composed of silt, sand, gravel, cobble and/or bedrock. (Atkins-Omniplan)

A STRESS FUNCTION FOR EVALUATING STRATEGIES FOR WATER QUALITY MANAGEMENT,
Illinois Natural History Survey, Urbana.
W. U. Brigham, and D. L. Hey.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-109828, Price codes: A06 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-217, October, 1981. 4 p, 1 Tab. R-805614-01-0

Descriptors: *Water quality management, *Computer models, *Toxicity, *Water pollution effects, *Bluegills, *Stress, Carp, Aquatic environment, Ammonia, Seasonal variation, Combined sewer overflows, Oxygen demand, Effluents, Residual chlorine, Fish.

This investigation explores the relationship between biological communities and the physical and chemical conditions in the aquatic environment. Seasonal patterns and the duration and probability of the occurrence of chemical conditions and physicial events are established by means of computer modelling. An instantaneous measure of stress is calculated by summing the decimal fractions of the 96-hr lethal concentrations (for bluegills) of each of 21 toxicants. These data are summarized as a quasicontinuous stress function calculated over 1-hr intervals. The stress function is related to five distinct biological communities ranging from the most to the least tolerant of pollution. Data from a test watershed in northeastern Illinois yielded stress functions as follows: 0.120 to 783.7 (mean 23.02) from a site with no fish, 0.155 to 98.47 (mean 1.038) from a site with a carp population, and 0.005 to 0.279 (mean 0.116) from a site with a bass population. A hypothetical management plan to reduce the ammonia component at the no-fish site was incorporated into the stress function. This plan limited effluent ammonia concentrations to 1.5 mg/liter during summer months and 4.0 mg/liter during the winter, eliminated combined sewer overlflows, reduced sediment oxygen demand levels substantially, and increased dissolved oxygen levels moderately in treatment plant effluents. Mean stress was reduced from 23.02 to 2.12- more than an order of magnitude. This level was still significantly higher than that of the carp site, primarily because of residual chlorine in the effluents from wastewater treatment plants. These results suggest that if species other than carp are desired in the fishery, further control strategies might need to be implemented. (Author's abstract)

RELATIVE EFFECTS ON STREAM BIOTA OF CHLORINE AND AMMONIA OCCURRING IN SECONDARY SEWAGE,
Southern Illinois Univ. at Carbondale.
W. M. Lewis, R. C. Heidinger, M. H. Paller, and L. J. Wawronowicz.
Document No 81/35, November, 1981. Illinois Department of Energy and Natural Resources. 253 p, 19 Fig, 12 Ref, 14 Append.

Descriptors: *Chlorine, *Ammonia, *Residual chlorine, *Effluents, *Secondary wastewater treatment, Fish toxins, Dissolved oxygen, Turbidity, Fish populations, Algal control, Invertebrates, Stream biota, Water pollution, Streamflow, Toxicity, Pollutants, *Illinois, Water quality standards.

According to Illinois pollution standards, sewage treatment plants cannot legally dischange an effluent which elevates stream total ammonia levels above 1.5 mg/l. Prior studies suggest that chlorine added to secondary sewage effluent as a disinfectant is the principal environmental toxicant, not ammonia, as was previously thought. This study examined the relative effects of the two pollutants. Three streams receiving chlorinated secondary sewage were monitored for significant biotic and abiotic variables. After a year, chlorination was stopped to observe any changes that might occur when only ammonia was present. It was found that eliminating residual chlorine from god quality secondary sewage effluents will result in quantitative and qualitative restoration of fish communities. Further conclusions were that eliminating residual chlorine from poor quality sewage effluents will not necessarily revive fish communities; that high ammonia-nitrogen concentrations did not affect the distribution of fishes in these three streams (but might in high quality streams with much pollution-sensitive taxa); that effluent turbidity can limit fish distribution; that cessation of chlorination did not result in excessive algal growth and significant decreases in dissolved oxygen if effluent quality is good and flow rates are moderately high; that invertebrate communities may show favorable quantitative but not qualitative responses to chlorination cessation in good quality secondary sewage effluent; and that the effects of highly toxic sewage may be more severe in winter than in summer. In most cases, cessation of chlorination will be environmentally more beneficial than tertiary ammonia removal. (Atkins-Omniplant)

THE ECOLOGICAL SIGNIFICANCE OF A STUNTED WHITE PERCH POPULATION IN AN EUTROPHIC MAINE POND,
Maine Univ. at Orono. Land and Water Resources Center.
R. Hines.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-211517, Price codes: A04 in paper copy, A01 in microfiche. MS Thesis, May, 1981. 45 p, 8 Fig, 10 Tab, 61 Ref, 1 Append. OWRT B-018-ME(1).

Descriptors: Fish food organisms, Fish management, *Fish populations, *Eutrophic lakes, Food chains, *Perch, Trophic level, *Growth rates, White perch, Hermon Pond, *Maine, Ecological effects.

A study was conducted to evaluate the ecological role of an abundant white perch (Morone americana Gmelin) population in an eutrophic pond, Hermon Pond, Maine. Data on growth and feeding habits for this population were combined with published literature to construct food web models for the pond community. The responses of these model systms to the manipulation of fish stocks were predicted using loop analysis with special attention being paid to those changes that would affect fishing and water quality. The diet composition of yearling-plus white perch varied markedly with season and size. In August and September, 1979, and in July, 1980, perch less than 220 mm fed largely on the aquatic larvae and pupae of Diptera. In May, 1980, the diet was a mixture of immature insects and cladocerans. By June, these perch were feeding mainly on daphnids. White perch larger than 220 mm were largely piscivorous. Growth and age determinations indicated that the white perch population was characteristically stunted. The growth rate of white perch in the study population was slow when compared with growth rates reported for populations in other waters; however overabundant and stunted populations are common in many other areas. Several studies indicate that predation pressure may counteract the species' tendency to overpopulate and stunt. Loop analysis of the seasonal food web models suggests that management efforts for white perch should be directed at reducing the number of young-of-the-year. The introduction of an openwater piscivore may be a way to implement this strategy in eutrophic Maine waters.

HEALTH EFFECTS OF ALTERNATE DISINFECTANTS AND THEIR REACTION PRODUCTS,
Environmental Protection Agency, Cincinnati, OH.
R. J. Bull.
Journal of the American Water Works Association, Vol 72, No 5, p 299-303, May, 1980. 10 Tab, 19 Ref.

Descriptors: *Disinfection, *Water treatment, *Chlorinated hydrocarbons, *Toxicity, Water pollution effects, Chlorination, Chlorine dioxide, Ozone, Chlorine, Chloramine, Drinking water, Organic compounds, Carcinogens, Public health, Chlorites, Trihalomethanes, Reviews.

The health effects of the water disinfectants, chlorine dioxide, chloramines, and ozone, are reviewed. Many studies concentrated on chlorine dioxide and its inorganic byproducts, chlorite and chlorate. Chlorite produces methemoglobinemia in humans and laboratory animals. Unlike nitrite, chlorite is hemolytic. Similar changes are produced by chlorate, but the observed changes disappear with continued exposure after 2 months. No significant effects of 5 mg per liter chlorite in drinking water were observed in the population of a small town. However, red cell glutathione and 2,3-diphosphoglyceric acid were not determined. One individual with glucose-6-phosphate dehydrogenase deficiency showed 15% decreases in hemoglobin and hematocrit during the period when chlorite was used for disinfection. Rats exposed to monochloramine in drinking water at concentrations up to 100 mg per liter for 45 days showed no overt adverse effects. However, patients undergoing kidney dialysis with chloramine-treated water suffered acute hemolytic anemia. The organic reaction products of disinfectants include trihalomethanes, known carcinogens. One study investigated the susceptability of mice to tumors produced by painting the skin with tumor promotors and disinfected Ohio River water concentrated by a factor of 102-186 by reverse osmosis, which does not concentrate trihalomethanes, but higher molecular weight compounds. No tumors were produced by nondisinfected water or water treated with chlorine dioxide plus tumor promotor. Tumors were produced by disinfection reaction products plus tumor promotors as follows: chlorine, 4 of 25 animals; chloramine, 5 of 25 animals; and ozone, 7 of 25 animals. (Cassar-FRC)

EFFECTS OF PETROLEUM HYDROCARBONS ON PLANT LITTER MICROBIOTA IN AN ARCTIC LAKE,
Cincinnati Univ., OH. Dept. of Biological Sciences.
V. L. McKinley, T. W. Federle, and J. R. Vestal.
Applied and Environmental Microbiology, Vol 43, No 1, p 129-135, 1982. 4 Fig, 32 Ref.

Descriptors: *Lakes, *Hydrocarbons, Biomass, Arctic, Polar regions, *Environmental effects, Arctic zone, Microbiological studies, Leaves, Microorganisms, Plant litter, Oil, *Toolik Lake, *Alaska.

The short term effects of Prudhoe Bay crude oil, diesel fuel, and toluene on microbial adenosine triphosphate (ATP) levels and the rate of acetate incorporation into microbial lipids on colonized Carex sedge leaf litter were examined. Study was also made of the effects of Prudhoe Bay crude oil, motor oil, diesel fuel, gasoline, hexane, and toluene on Carex lignocellulose mineralization by Toolik Lake sediments. Microbial metabolic activity, measured as the rate of acetate incorporation into lipid, did not vary significantly from controls over a 12 hr period after exposure of colonized Carex litter to 3.0 ml of Prudhoe Bay crude oil, diesel fuel, or toluene per liter. ATP levels were elevated within 2 hr after exposure to diesel fuel or toluene, but returned to control levels after 4 to 8 hr. Mineralization of specifically labeled lignocellulose by Toolik Lake sediments was inhibited 58, 67, 67, and 86% by exposure to diesel fuel, motor oil, gasoline, and toluene, respectively. Hexane-treated samples displayed an increase in the rate of lignocellulose mineralization of 33%. Mineralization of the labeled lignin component of lignocellulose appeared to be more sensitive to hydrocarbon perturbations than was the labeled cellulose component. (Baker-FRC)

EFFECT OF WATER POLLUTANTS AND OTHER CHEMICALS UPON THE ACTIVITY OF LIPASE IN VITRO,
Environmental Research Lab.-Duluth, MN.
G. M. Christensen, and B. Riedel.
Archives of Environmental Contamination and Toxicology, Vol 10, No 3, p 357-363, 1981. 2 Tab, 9 Ref.

Descriptors: *Pollutants, *Water pollution effects, *Enzymes, Mercury, *Heavy metals, Chemical reactions, *Lipids, Organic compounds, Inorganic compounds, Pesticides.

Lipase is an important lipid enzyme which may be particularly vulnerable to some highly lipid-soluble environmental chemicals which bioaccumulate in lipid-rich tissue when their rates of degradation or elimination are relatively slow. This study investigated the effects of 100 organic and inorganic chemicals representative of some of the major types of chemical water pollutants on lipase activity. The chemicals tested included thiomides, thiocarbamates, organothiophosphates, urea derivatives, antibiotics and other biocides, aromatic halogenated hydrocarbons, aliphatic halogenated hydrocarbons, phenols and halophenoxy acids, solvents and other industrial chemicals, inorganic salts (both active cations and active anions), organo-metals, carcinogens, and several miscellaneous chemicals. The mercuric ion was found to have the strongest inhibitory effect, followed by other heavy metals, pentachlorophenol, and dicofol. The enzyme was generally found to be relatively highly sensitive to many of the heavy metal cations that are toxic to aquatic animals. Chlorinated phenols and chlorobenzene pesticides were the most inhibiting of the organic chemicals tested, followed by warfarin and malathion. Organometals, phenyl mercuric chloride, and methyl mercuric chloride had intermediate inhibitory effects. Some anions usually considered fairly toxic were found to have only a slight or negligible effect. The four organic carcinogens tested were relatively uninhibiting. The inhibitory effect of a mixture of 10 inorganic salts on lipase was shown to develop through an accumulation of the effects of the components. None of the chemicals studied caused a measurable activation of the enzyme. (Carroll-FRC)

Descriptors: *Lakes, *Lake restoration, *Macrophytes, Aquatic plants, *Water pollution effects, *Industrial wastes, Petroleum industry, Mapping, Comparative productivity, Bulgaria.

Higher macrophyte vegetation was completely destroyed by dredging operations and oil pollution in the collecting ponds at Poda, which received wastes from a petroleum plant in 1963-1971. Following the construction of a biological treatment plant in 1972, the water purity improved, and gradual restoration of the macrophytes began. The restoration process was followed by mapping, and began in 1973 with the appearance of single Phragmites communis L. at the edges of the lake. In 1974 Typha angustifolia and Bolboschoemus maritimus L. also appeared. By 1978 the vegetation covered 16.2% of the fourth lake. The greatest annual vegetation increase, 8.36%, was seen in 1975. Phragmites communis L. showed the most rapid recovery, accounting for 98.37% of the surface currently covered by vegetation. The stem height and diameter as well as the biological productivity of Phragmites communis were lower than in control lakes. The other two species recovered more slowly.

CYTOGENETIC EFFECTS ON THE EASTERN MUDMINNOW, UMBRA PYGMAEA, EXPOSED TO ETHYL METHANESULFONATE, BENZO(A)PYRENE, AND RIVER WATER,
Nijverheidsorganisatie TNO, Delft (Netherlands).
R. N. Hooftman, and G. J. Vink.
Ecotoxicology and Environmental Safety, Vol 5, No 3, p 261-269, 1981. 1 Fig, 5 Tab, 18 Ref.

Descriptors: *Fish, *Mudminnow, *Mutagens, *Water pollution effects, *Ethyl methanesulfonate, Benzopyrene, Rivers, *Rhine River, Bioindicators, Aromatic compounds, Organic compounds.

The eastern mudminnow, Umbra pygmaea, was a suitable bioindicator for detecting cytogenetic effects of chemical pollutants in the aquatic environment. Groups of fish were exposed to two known genotoxic agents, ethyl methanesulfonate and benzo(a)pyrene, and to polluted Rhine River water sampled near Lobith, the Netherlands. Best results were obtained with gill tissue after 2 injections with bromodeoxyuridine. Chromosome damage was found in fin and gill tissue. Chromatid aberrations were most common, but chromosome breaks were also found. A 2-day exposure to ethyl methanesulfonate at concentrations of 0, 18, 40, and 200 mg per liter produced 0.3, 1.1, 6.8, and 19.6% metaphases with chromosome aberrations, respectively. Benzopyrene at concentrations of 0.00001 mg per liter produced no metaphase aberrations. At the 0.0001 mg per liter level, exposures of 2, 4, and 6 days gave aberrations of 0.3, 1.5, and 1.8%, respectively. Rhine River water caused 0.7, 2.5, and 4.1% metaphases with chromosome aberrations at 8 days exposure to water diluted by high flow, and 8 and 14 days exposure to less diluted low flow water, respectively. Sister chromatid exchange induction analysis after 8 days exposure to Rhine River water produced fin and gill metaphase aberrations of 7.0-8.4% and 5.0-5.2%, respectively, compared with the control, 2.2-2.7%. EFFECTS OF LAND USE ON SURFACE-WATER QUALITY IN THE EAST EVERGLADES, DADE COUNTY, FLORIDA,
Geological Survey, Tallahassee, FL. Water Resources Div.
B. G. Waller.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-176520, Price codes: A03 in paper copy, A01 in microfiche. Geological Survey Water-Resources Investigations 81-59, 1982. 37 p, 2 Fig, 22 Tab, 7 Ref.

Descriptors: *Land use, *Surface water, *Water quality, *Environmental effects, Agricultural chemicals, Runoff, Wetlands, Nutrients, Data collections, Water pollution effects, Pesticides, Bacteria, *Florida, *Dade County, Everglades.

Water-quality characteristics were determined at five developed areas in the East Everglades, Dade County, Florida, during the 1978 wet season (June through October). These areas are designated as: Coopertown; Chekika Hammock State Park; residential area; rock-plowed tomato field; and Cracker Jack Slough agricultural area. Data from the developed areas were compared with data from four baseline sites in undeveloped areas to determine the effects of land use on the surface-water quality. The rock-plowed tomato field was the only area where surface-water quality was affected. Water quality at this field is affected by agricultural activities and chemical applications as indicated by increased concentrations of orthophosphate, organic nitrogen, organic carbon, copper, manganese, mercury, and potassium. The remaining four areas of land use had water-quality characteristics typical of baseline sites in nearby Northeast Shark River Slough or Taylor Slough. Chemical analyses of soil indicated chlorinated-hydrocarbon insecticide residues at Coopertown and the two agricultural areas, Cracker Jack Slough and the rock-plowed tomato field. Trace elements in concentrations greater than base level occurred at both agricultural areas (manganese), Chekika Hammock State Park (manganese), and at Coopertown (lead and zinc). (USGS)

MEAN ANNUAL STREAMFLOW OF SELECTED DRAINAGE BASINS IN THE COAL AREA OF SOUTHEASTERN MONTANA,
Geological Survey, Helena, MT. Water Resources Div.
R. F. Ferrieria.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-137696, Price codes: A03 in paper copy, A01 in microfiche. Geological Survey Water-Resources Investigations 81-61, October, 1981. 21 p, 5 Fig, 5 Tab, 13 Ref.

Descriptors: *Streamflow, *Coal mines, *Irrigation effects, Evaluation, Forecasting, Flow characteristics, Surface runoff, Land use, Data collections, *Montana, *Fort Union coal region.

Streamflow characteristics of drainage basins within the Forst Union coal region of southeastern Montana were estimated to provide premining data for evaluating the future effects of mining on the environment. Estimated annual mean streamflow at 22 data-collection stations for water years 1975-77 ranged from 0 to 887 cubic feet per second. These estimates are based on miscellaneous-streamflow records at each station and continuous-streamflow records from other stations in the study area. Estimated mean annual streamflow for a 10-year period (water years 1968-77) ranged from 0 to 572 cubic feet per second. These long-term estimates were based on data from stations in the surrounding area having continuous-streamflow records. Estimates mean annual runoff in inches for selected drainage basins within the study area showed no discernible pattern. Many of the drainage basins had a mean annual runoff of less than 0.60 inch; the maximum observed mean annual runoff was 4.45 inches. (USGS)

AN ANNOTATED KEY TO THE IDENTIFICATION OF COMMONLY OCCURRING AND DOMINANT GENERA OF ALGAE OBSERVED IN THE PHYTOPLANKTON OF THE UNITED STATES,
Geological Survey, Reston, VA. Water Resources Div.
P. E. Greeson.
Available from Supt. of Documents, GPO, Washington, DC 20402, Price, $4.75. Geological Survey Water-Supply Paper 2079, 1982. 138 p, 58 Fig, 4 Tab, 123 Ref.

Descriptors: *Algal, *Phytoplankton, *Taxonomy, *Water quality, Hydrologic data, United States, Genera, *Genera identification.

In early 1979, a retrieval was made for all phytoplankton data contained in the computerized data file of the U.S. Geological Survey. The retrieval revealed the analytical results of 17,959 samples collected and processed between October 1973 and October 1978. Of the approximately 500 genera of fresh-water algae reported in the United States, the U.S. Geological Survey observed 321 genera in the phytoplankton. Fifty-two genera were considered to be commonly occurring and 42 genera were considered to be community dominants. The report lists, describes, and provides a detailed taxonomic key for the identification of 58 genera of algae considered either commonly occurring or dominant. Also included is a summary of environmental conditions under which each algal genus was observed, as well as a glossary and an extensive list of selected references. (USGS)

TOXICITY OF NITRITE TO LARVAE OF THE SALAMANDER AMBYSTOMA TEXANUM,
North Texas State Univ., Denton. Dept. of Biological Sciences.
D. W. Huey, and T. L. Beitinger.
Bulletin of Environmental Contamination and Toxicology, Vol 25, No 6, p 909-912, 1980. 1 Tab, 16 Ref.

Descriptors: *Nitrites, *Salamanders, *Toxicity, Water pollution effects, Nitrogen compounds, Mortality, Aquatic animals, Texas, Ponds.

Larvae of the salamander, Ambystoma texanum, from a Texas pond were highly sensitive to nitrite in low chloride (5.0 mg per liter) water. The 96 hour LC50 was 1.09 mg per liter nitrite. Nearly 100% mortality was seen at concentrations of 2.5 mg per liter nitrite and above. In water containing 300 mg per liter chloride and 10 mg per liter nitrite, no mortality was observed in 96 hours, probably as a result of lower nitrite uptake rates. (Cassar-FRC)

A METHOD FOR DETERMINING STRESS IN WETLAND PLANT COMMUNITIES FOLLOWING AN OIL SPILL,
Louisiana State Univ., Baton Rouge. Center for Wetland Resources.
C. J. Smith, R. D. DeLaune, and W. H. Patrick, Jr.
Environmental Pollution, Series A: Ecological and Biological, Vol 26, No 4, p 297-304, December, 1981. 2 Fig, 2 Tab, 16 Ref.

Descriptors: *Marsh plants, *Stress, *Sublethal effects, *Carbon dioxide, Photosynthesis, Toxicity, Marshes, Spartina, Ecosystems, Plant pathology, Wetlands, *Oil spills, Gas chromatography, Water pollution effects, *Ecological effects.

A portable gaseous exchange chamber was developed to measure sublethal stress, such as the effects of oil spills, in wetland plant communities. The system, which requires no on-site electricity, was tested in Louisiana salt marsh on Spartina alterniflora by measuring carbon dioxide fixation rates. Stresses studied were manmade (two concentrations of crude oil) and natural (streamside and inland location). The procedure involved placing light and dark chambers adjacent to each other on marsh plants for about 20 min. Air samples were taken every 5 min and analyzed for carbon dioxide by a gas chromatograph equipped with a flame ionization detector and a catalytic conversion unit to quantitatively reduce CO2 to CH4. The samples were analyzed within 24 hours after collection in an off-site laboratory. After 7 and 14 days exposure the oil-treated plants had fixation rates 19-37% of those in the control plants. In the plants suffering natural water stress, the shorter inland plants had carbon fixations equal to 27-34% of that of the taller streamside plants. (Cassar-FRC)

NITRIFYING POPULATION DENSITIES AND INHIBITION OF AMMONIUM OXIDATION IN NATURAL AND SEWAGE-ENRICHED CYPRESS SWAMPS,
Florida Univ., Gainesville, Dept. of Environmental Engineering.
F. E. Dierberg, and P. L. Brezonik.
Water Research, Vol 16, No 1, p 123-126, January, 1982. 1 Fig, 2 Tab, 16 Ref.

Descriptors: *Nitrification, *Wastewater disposal, *Bacteria, Cypress, Water pollution effects, Organic matter, Ammonium, Oxidation, Nitrates, Swamps, Peat, *Florida.

The densities of autotrophic nitrifiers in peat from the floors of cyress domes near Gainesville, Florida, were investigated. One dome received groundwater from a deep artesian aquifer, two were amended with secondary treated sewage effluent, and a fourth was left in the natural state. Nitrifying bacterial densities as determined by the most probable number method (in cells per ml) were as follows: groundwater dome, 78-7900; sewage domes, 350->160,000; and natural dome, 0-56. mmonium concentrations (in mg per liter) were as high as 24.5 in the sewage domes, 3.8 or less in the groundwater dome, and 0.55 or less in the natural dome. Water from the natural dome was used for nitrification rate studies. It was determined that the low pH (4-5) and not dissolved humic materials was responsible for nitrification inhibition. The pH value of the sewage domes was 6-7, more favorable for nitrification. Nitrification inhibition, as seen in natural cypress domes, prevents N losses in these ecosystems because ammonium ion, the dominant inorganic N species, does not leach from the root zone as readily as nitrate. (Cassar-FRC)

SEASONAL VARIATIONS IN PRIMARY PRODUCTION IN SURFACE WATERS OF THE SAGUENAY RIVER (VARIATIONS SAISONNIERES DE LA PRODUCTION PRIMAIRE DANS LES EAUX DE SURFACE DE LA RIVIERE DU SAGUENAY),
Quebec Univ., Chicoutimi. Dept. des Sciences Pures.
R. Cote.
Hydrobiologia, Vol 83, No 1, p 1-10, 1981. 2 Fig, 3 Tab, 19 Ref. English Summary.

Descriptors: *Water pollution effects, *Primary production, *Seasonal effects, Population dynamics, *Chlorophyll, Rivers, Saguenay River, *Heavy metals, Industrial wastewater, Phytoplankton, Tides, River flow.

Seasonal variability of chlorophyll a and primary production rates were investigated at a station on the Saguenay River near Chicoutimi, May-December, 1978. The annual mean flow in the Saguenay may reach 1300 cu m per sec, and surface tides in the range of 4-6 m are present. At this station, with a maximum water depth of 20 m, the photic zone showed a maximum depth of 2 m. Phosphate levels were very low, with a seasonal mean of 0.02 + or - 0.02 microatom-gram per liter, and nitrates relatively high (mean of 5.6 + or - 0.75 microatom-gram per liter). Seasonal dynamics of the river are characterized by absence of a definite spring bloom, a late growth season, and persistently poor phytoplankton biomasses (chlorophyll a maximum of 3.7 mg per cu m). The maximum production rate was 3.5 mg C per cu m per hr, and the correlation between production rate and biomass was poor. This river flows through an industrialized region and receives effluents from metallurgical plants and paper mills, as well as urban runoff. The presence of trace metals (mercury, copper, lead and iron) may account to some degree for the inhibition of phytoplankton growth. (Carroll-FRC)

MICROBIAL ECOLOGY OF RIVER DEPOSITS IN THE RIVERS KENNET AND THAMES AT READING, ENGLAND,

Lyne and Martin Public Analysts, Reading (England).
R. M. Webster.
Process Biochemistry, Vol 16, No 6, p 12-15, 19, October/November, 1981. 3 Fig, 6 Tab, 24 Ref.

Descriptors: *Detritus, *Microbiological studies, *Aquatic plants, Rivers, *Kennet River, *Thames River, Epiphytes, Actinomycetes, Heterotrophic bacteria, Nutrients, Heavy metals, Algal growth, Aeromonas hydrophila, Toxicity, Indicators, Eutrophication, Water pollution effects, *England.

Surveys were conducted on the microbiology of detritus and sediments of the rivers Kennet and Thames. The first survey, in 1974, estimated populations of algae, fungi, yeasts, blue-green algae and bacteria in different detritus and sediment samples. The second survey, in 1979, estimated the populations of heterotrophic bacteria and actinomycetes on the epiphytic detritus accumulated on the leaves of Nuphar lutea, the yellow water lily, and on the benthic detritus of reed beds, indicated in the first studies as sites of high microbial activity. A simplified succession pattern indicates that peaks of yeasts, blue-green algae, Chromobacterium and total bacteria (by microscopic count) are associated with algal peaks in the summer. Peaks of heterotrophic bacteria and micromonosporas which followed the algal peaks were probably stimulated by decay of the algae. During a bloom the greatest increase in numbers was due to Aeromonas hydrophila. The presence of heavy metals inhibited microbial growth in some of the samples. In addition to relatively high levels in May when the sediments were stirred up, heavy metal levels increased to a peak at the end of October, at which time the number of yellow colonies did not increase with the peak of total heterotrophic bacteria. Although interactions appear to exist between nutritional and metabolic stresses, it seems potentially interesting to use A. hydrophila as a bacterial indicator of organic and heavy metal pollution. The ATP assay could also be used as an indicator of toxicity. (Carroll-FRC)

AN INTEGRATED WATER-QUALITY INDEX FOR IRRIGATION USE,
Central Groundwater Board, Lucknow (India).
B. K. Handa.
Indian Journal of Agricultural Sciences, Vol 51, No 6, p 422-426, June, 1981. 2 Tab, 12 Ref.

Descriptors: *Water quality, *Irrigation water, Monitoring, Salinity, *Soil contamination, *Plant toxins, *Hazardous materials, Water pollution effects, Mathematical studies.

A water quality index has been developed which takes into consideration the effect of various constituents present in water on its use for irrigation. These constituents were divided into two categories: those that are highly toxic to plants and humans, and those that adversely affect soil characteristics and plant growth and are also a health hazard to humans consuming those plants. The latter properties were further subdivided into several subgroups depending on their relative importance, and a ranking factor was assigned to each subgroup in order of importance. For all waters that presented high salinity and other hazards the index was negative. When positive values of the index were obtained, it was taken to indicate that the water so rated could be used for irrigation purposes. The index proved to be quite useful in comparing the overall quality of irrigation water from various sources. The index itself is very flexible and can be modified for various soils, crops, and irrigation techniques. (Baker-FRC)

PESTICIDES IN THE AQUATIC ENVIRONMENT,
Illinois Univ. at Urbana-Champaign.
D. A. Belluck.
PhD Thesis, 1981. 153 p, 15 Fig, 32 Tab, 159 Ref, 7 Illust. University Microfilms International, Ann Arbor, MI; Order No GAX81-14387.

Descriptors: *Aquatic environment, *Pesticides, *Water pollution effects, Aquatic life, Toxicity, Bioassay, Surface water, *Caddisflies, *Eggs, Organochlorine pesticides, Triaenodes tardus, *Illinois, Xenobiotics.

Organochlorine pesticide data of samples obtained from Clear Creek (Southern Illinois) and Lodge Pond (Central Illinois) are presented. Organochlorine pesticide residue levels in organisms from both aquatic communities suggest that residue concentrations may be primarily determined by the habitat and detoxification capabilities (or biological properties) of an organism rather than by its trophic level position. A new bioassay, the caddisfly egg toxicity bioassay, has been developed to measure the effects of zenobiotics on caddisfly embryogenesis. Results from this bioassay indicate that certain insecticides and herbicides are embryotic and/or teratogenic to eggs of the caddisfly, Triaenodes tardus. Bioconcentration of pesticides by T. tardus egg masses is correlated with the physiochemical properties of the pesticide. A strong correlation exists between water solubility and bioconcentration factor. Passive biological system such as caddisfly eggs can accumulate significant quantities of pesticiede from water. Within 24 hours of exposure to radiolabelled pesticides, egg mass pesticide concentrations were at least equal to that in the surrounding water. The caddisfly egg toxicity bioassay provides a quick (three weeks or less), sensitive and inexpensive technique for use by researchers to determine the effects of xenobiotics on aquatic organisms. This new bioassay enables a biologist to test the unique genetic endowment of a local insect population for resistance or susceptibility to a given compound. (Sinha-OEIS)

Zeitschrift fur Wasser und Abwasser Forschung, Vol 14, No 5/6, p 188-193, 1981. 3 Fig, 5 Tab, 4 Ref.

Descriptors: *Wastewater treatment, *Phosphate removal, *Adsorbents, Activated alumina, Pilot plants, Process control, Chemical recovery, Regeneration, Aluminum compounds, Advanced wastewater treatment, Germany.

Prior experiments had revealed the potential usefulness of activated alumina for removing phosphate from wastewaters in a form suitable for recovery. A pilot plant was constructed on the experimental field of the Federal Health Bureau in Berlin to test this process on secondary effluent. The plant comprised four stirring reactors with a volume of 0.44 cu m each, of which three were in use for phosphate adsorption while the fourth was being switched to regeneration of activated alumina. Each reactor is filled with 50 kg of activated alumina.. An automatically operating Phosphatometer measures the phosphorus content in the effluent from each reactor, and when the concentration exceeds 1 mg/liter, a process computer switches the reactor over for regeneration with NaOH solution. The intake line is equipped with a turbidimeter to detect sludge influx during heavy rains. A pressure monitor detects obstructions in the process line, and a pH meter regulates carbon dioxide addition for pH adjustment. An effluent turbidimeter indicates alumina carryover. In trials conducted from November 1980 to April 1981, uniform effluent quality was achieved despite influent phosphorus fluctuations. Approximately 40% reductions in COD and 20% reductions in DOC were also achieved in the alumina step. Regeneration efficiencies were only 60% instead of the anticipated 80%; however, this did not greatly increase operating costs. Alumina losses during regeneration were about 4%. Mean effluent concentrations in the range of 0.6-0.7 mg/liter P were obtained over the trial period. (Carroll-FRC)

Zeitschrift fur Wasser und Abwasser Forschung, Vol 14, No 5/6, p 218-223, 1981. 8 Fig, 2 Tab.

Descriptors: *Wastewater treatment, *Toxicity, *Retention basins, *Heavy metals, Sulfides, Chemical precipitation, Iron compounds, Automation, Process control, *Industrial wastewater, Copper, Zinc, Chromium, Cyanide, Biological wastewater treatment, Diversion, Germany.

Studies were conducted from May 1978 to June 1980 at the Geislingen/Steige wastewater treatment plant regarding the possibility of protecting the biological treatment stage from toxicants with the aid of stormwater dention basins. Recurrent reductions in protozoan populations and impairment of activated sludge settling indicated the influx of toxicants into this plant. In many cases, the heavy metal contents of the filter cake and the activated sludge exceeded the permissible levels for agricultural land disposal. A toxicant warning system was installed, consisting of pH, conductivity and temperature sensors, turbidimeter, Toximeter, and photometers for measuring chromium (VI), copper, zinc, cyanide, oils and grasses. If limiting values for any of these indices are exceeded, a slide valve preceding the treatment plant diverts the wastewater into the stormwater detention basin. A procedure for treating the diverted water at reasonable expense was also developed. Sulfide precipitation was the only practical method found for removing copper and zinc, in the presence of complexants, while 97-99% elimination of chromium(VI) was achieved by sequential addition of iron(II) and iron(III) compounds. The diversion technique was judged reasonably effective; however, the high cost of chemical treatment means that this treatment should not be considered a 'normal' part of the wastewater treatment process. Instead, the industrial dischargers must improve effluent quality so that special treatment will only be required in emergencies. (Carroll-FRC)

WASTEWATER TREATMENT WITH ACTIVATED CARBON ADDITION AT THE AERATION STAGE AND SPENT CARBON REGENERATION. (ABWASSERREINIGUNG UNTER ZUGABE VON AKTIVKOHLE IN DIE BELEBUNGSSTUFE UND REGENERIERUNG DER AKTIVKOHLE),
Uhde (Friedrich) G.m.b.H., Dortmund (Germany, F.R.).
K. Eisenacher, U. Neumann, and J. Kelin.
Zeitschrift fur Wasser und Abwasser Forschung, Vol 14, No 5/6, p 168-173, 1981. 11 Fig, 2 Ref.

A wastewater discharging concern, a chemical plant construction company, and a research institution performed a cooperative study aimed at demonstrating the advantages of continuous addition of powdered activated carbon in the biological purification of wastewaters containing refractory organic materials. A pilot plant was constructed, treating

LIBRARY U. OF ILL. URBANA CHAMPAIGN

wastewater from the Griesheim plant of the Hoechst Co., previously subjected to neutralization and sedimentation. Two activated sludge treatment units were used, one with and one without powdered activated carbon. The wastewater contained aliphatic and aromatic, chlorinated and nitrated organic compounds in amounts varying with production demand. Effluent TOC values of 175-355 mg/liter were attained following activated sludge treatment without active carbon, compared to values of 50-128 mg/liter for fresh active carbon addition at 100 mg/liter of wastewater. A visible improvement in effluent clarity was achieved. During some experimental periods, normal operation of the biological treatment plant without carbon addition was impossible. To reduce the cost of treatment, an experimental carbon regeneration plant was constructed. The mixture of excess sludge, spent carbon and wastewater was collected, mechanically dewatered, and the carbon regenerated. Adequate reactivation was accomplished for several cycles by desorption with stream at 150-200 degrees C, but then a more rigorous treatment was required, comprising desorption at higher temperatures and reactivation in an inert gas (fluidized sand bed) at temperatures above 800 degrees C. COMBINATION OF MACROPOROUS RESINS AND ACTIVATED CARBON IN ADVANCED WASTEWATER TREATMENT. (KOMBINATION VON MAKROPOROSEN ADSORBERHARZEN MIT AKTIVKOHLE ZUR WEITERGEHENDEN ABWASSERREINIGUNG),
Hanover Univ. (Germany, F.R.). Inst. fuer Siedlungswasserwirtschaft.
H. Ruffer, and T. Slomka.
Zeitschrift fur Wasser und Abwasser Forschung, Vol 14, No 5/6, p 176-180, 1981. 6 Fig, 2 Tab, 12 Ref.

Descriptors: *Wastewater treatment, *Activated carbon, *Resins, Municipal wastewaters, Organic compounds, Recycling, Regeneration, Filtration, Total organic carbon, *Macroporous resins.

Combining weakly basic ion exchange resins and active carbon for treatment of municipal wastewaters would reduce costs by prolonging carbon life and increasing adsorber performance. A test system was constructed comprising multilayer (gravel/sand/anthracite) filtration, macroporous resin adsorption, and activated carbon adsorption, with the possibility of removing samples for analysis after each treatment stage. A high-quality regenerable carbon produced more complete removal of organic materials than an inexpensive, disposable carbon. Using a biologically pretreated feed water, the initial TOC 26.4 mg/l decreased to 20.6 g/liter following filtration, 11.8 mg/liter following resin adsorption, and 6.14 mg/l after treatment with the regenerable carbon. Effluent quality remained constant up to the breakthrough point of the column, which was reached after 6000 bed volumes had passed through. Subsequent chlorination gave water of excellent quality for industrial use. The problem of disposal and cost of the regenerant solution had previously interfered with practical use of resin adsorption. The regeneration eluate should not be discarded, as it can be reused up to 8 times. Eluate volume for disposal was reduced to about 1 cu m/10,000 cu m of wastewater treated by allowing a diffusion interval, i.e., allowing the regenerant to remain in contact with the resin for a few hours early in the regeneration process. The most heavily contaminated regenerant fractions were discharged to the biological water treatment plant, and the remainder reused. (Carroll-FRC)

CHRYSLER UPGRADES OILY WASTES TREATMENT IN KOKOMO,
Chrysler Corp., Kokomo, IN.
B. D. Harlow, and T. M. Doran.
Industrial Wastes, Vol 27, No 6, p 24-27, November/December 1981. 2 Fig, 2 Tab.

Descriptors: *Industrial wastewater, *Oily water, *Wastewater treatment, Freon, *Separation techniques, *Metal-finishing wastes, Chrysler Corporation.

The Chrysler Corporation plant in Kokomo, Indiana, has upgraded its waste treatment plant to reduce the concentration of freon extractable compounds to less than 50 mg per liter prior to discharge into the city sewer system. The facility makes and assembles cast aluminum transmission parts. These processes require large quantities of oil. Problems with the original treatment facilities were inadequate batch tank capacity, inefficient chemical feed system, only a single flotation unit, necessity for a separate low grade oil processing system, and a large volume of water. Modifications included use of an emulsion breaker, addition of a batch treatment tank, oil/water separator tank, oil pre-heat tanks, and filtered oil tank; pH adjustment; and elimination of a flotation unit and oil cookers. Reclaimed oil is sent elsewhere for additional refining or storage on-site. current effluent freon extractables are 21 mg per liter compared with 80 mg per liter in 1976. The volume of liquid treated has been reduced from 10.8 million gal per month to 7.6 gal per month, alum dose from 602 to 58 mg per liter, polymer dose from 9.7 to 1 mg per liter, chemical costs from $11,573 to $2,437 per month, and cost per 1000 gal from $1.07 to 33 cents. No waste oils are generated by the modified process, whereas 10,000 gal per week were formerly produced for disposal at 10 cents per gal. (Cassar-FRC)

IMPACT OF PHOSPHORUS REMOVAL AT THE DANBURY, CONNECTICUT SEWAGE TREATMENT PLANT ON WATER QUALITY IN LAKE LILLINONAH,
Colorado State Univ., Fort Collins. Dept. of Civil Engineering.
R. A. Jones, and G. F. Lee.
Water, Air, and Soil Pollution, Vol 16, No 4, p 511-531, 1981. 12 Fig, 5 Tab, 14 Ref.

Descriptors: *Water quality, *Phosphorus removal, *Water treatment facilities, Eutrophication, Lakes, Rivers, *Lake Lillinonah, Housatonic River, Filtration, *Danbury, Connecticut, *Wastewater treatment, Lake restoration.

This paper presents an independent assessment of the results of the FMC Corporation's limnological surveys made of Lake Lillinonah and Lake Zoar, an impoundment just downstream from Lake Lillinonah, and their major tributaries during the summers of 1976 and 1977. The surveys provide data which should help evaluate the effect of phosphorus removal at the Danbury wastewater treatment plant on water quality in the two lakes. The data revealed an apparent improvement in Lake Lillinonah water quality between the two years which might be related to phosphorus removal at the Danbury treatment plant. Phosphorus load was reduced from 13600 to 6700 kg/year in 1976 and 1977, respectively. The flows of the Housatonic River in 1976 and 1977 were also dissimilar: in 1977 about twice as much water entered Lake Lillinonah as in the former year. The eutrophication study results were used to estimate the impact of flow and altered phosphorus loads on Lake Lillinonah's eutrophication-related water quality. The average planktonic algal chlorophyll concentration would have been reduced from 35 to 30 micrograms/liter if the flows of the Housatonic River were to have been the same during the two years of the study. DESIGN MODELS FOR ADSOPRTION SYSTEMS IN WASTEWATER TREATMENT,
Queen's Univ., Belfast (Northern Ireland). Dept. of Industrial Chemistry.
G. McKay.
Journal of Chemical Technology and Biotechnology, Vol 13, No 2, p 717-731, 1981. 12 Fig, 69 Ref.

Descriptors: *Design criteria, *Water treatment facilities, Wastewater treatment, Mathematical models, Model studies, Simulation, Adsorption, Industrial wastes, Effluents.

Various methods of solid-liquid contacting in adsorption systems have been considered. High mass-transfer rates are obtained in fluidized bed systems, and small adsorbent particles may be used, giving a large external surface area for adsoprtion. The control of such systems is more difficult than of a fixed-bed column, and there is a lack of flexibility in operation. Fixed-bed adsorbers are most widely used, and the effluent continuously comes into contact with fresh adsorbent. Therefore the driving force to each equilibrium is high. In batch processes a relatively long contact time is needed to reach equilibrium and a further solid-liquid separation stage is needed at the end of the process. The selection of the correct adsorbent, the method of contacting and the regeneration system determine the economics of adsorption systems. Various methods of designing adsorption systems for wastewater treatment have been considered. The design of the reactivation unit is considered, and the technique of minimizing the cost of adsorption plants is discussed. It is usually wise in the design of wastewater treatment plants to allow some overdesign to account for certain factors, including flow rate surges, changes in feed concentration, increases in throughput requirements or increased levels of effluent quality, and for decreased adsorbent performance due to numerous reactivations. WATER TREATMENT AT HOMESTAKE'S BULLDOG MOUNTAIN OPERATION,
Homestake Mining Co., Creede, CO.
J. L. Young, and R. A. Bohling.
Mining Engineering, Vol 33, No 12, p 1689-1691, December, 1981. 4 Fig.

Descriptors: *Wastewater treatment, *Mine drainage, *Heavy metals, *Water quality standards, Hydrogen ion concentration, Mine wastes, Silver, Lead, Metals, Wastewater facilities, Aeration, Clarification, Filtration, Sand filters, *Colorado.

In 1977, a mine water treatment plant was constructed for Homestake's Bulldog Mountain silver and lead mines to keep discharge waters in line with National Pollutant Discharge Elimination System regulations. In 1980, construction began on a wastewater treatment plant. During treatment, mine discharge is first metered and then passed to the aeration stage. Metals are precipitated in a clarifier as hydroxides at pH 9.5-10.0 regulated by lime solution. The clarified effluent is sent to a splitter, where part of the stream may be treated by sand filtration. Sulfuric acid is used to make final pH adjustments to 6.0-9.0. Initial plant start-up problems were encountered with maintaining clarifier and final pH, effective lime pumping, and sludge removal. Most control problems were solved by a programmable Taylor 1380R adaptable gain controller. Daily assays from the plant show good compliance of discharge with permit parameters. High copper levels are occassionally encountered and are treated with hydrogen perioxide. Tests are in progress to study the feasibility of using O2 in place of sulfuric acid for effluent pH adjustment. (Geiger-FRC)

ZERO-DISCHARGE IN PRACTICE AT RAY D. NIXON POWER PLANT,
Ray D. Nixon Power Plant Water Supply, Colorado Springs, CO.
W. D. Givens, F. K. Marotte, and C. T. Zeien.
Industrial Water Engineering, Vol 18, No 5 p 20-25, September/October, 1981. 8 Fig.

Descriptors: *Cooling water, *Powerplants, *Water reuse, Water treatment, *Wastewater treatment, Water management, Water softening, Industrial wastewater, Algicides, Reverse osmosis, Evaporation, Ash, Solid waste disposal, Waste disposal, Water conservation, *Coal, Fuel, Water pollution prevention, Zero discharge, Colorado.

The Ray D. Nixon coal-fired power plant near Colorado Springs, Colorado, has successfully practiced zero-discharge water management since its opening in April 1980. The water comes from eight wells above a small brackish aquifer, which is

recharged from a nearby creek. Water softening by sodium-base ion exchange reduces the hardness. The treated water is stored in a 5.2 million gal steel reservoir until needed. Wastewater streams are equalized in a 10 million gal clay lined basin with 2 week detention time. Algae are controlled with simazine. The automated filtration system consists of three package units with capacities of 300 gpm each. Ferric chloride and a cationic polymer are used as flocculators. A 120,000 gal clear well provides filter backwash water and cushions flow changes. The remainder of the water treatment system consists of reverse osmosis, evaporators, decant basins, and evaporation ponds. (Cassar-FRC)

RECYCLING ALLOWS ZERO POWERPLANT WASTEWATER DISCHARGE,
B. B. Hall, and L. Stierwalt.
Industrial Water Engineering, Vol 18, No 5, p 26-30, September/October, 1981. 1 Fig, 5 Tab.

Descriptors: *Cooling water, *Powerplants, *Water reuse, *Wastewater treatment, Industrial wastewater, Water management, Ash, Solid waste disposal, *Waste disposal, Water conservation, Water pollution prevention, Clarifiers, Martin Drake Power Station, *Colorado Springs, Colorado, Zero discharge.

A zero discharge plant was designed for the coal-fired Martin Drake Power Station, Colorado Springs, Colorado, to comply with environmental regulations. A dual treatment system with limited interconnections was selected, one system to process ash transport water and the other to process cooling water blowdown. Fly ash and bottom ash are sent via the existing hydraulic transport system to new clarifiers for gavity settling. The ash transport water is reused for transporting more ash. Settled ash is trucked to a landfill. Cooling tower blowdown is treated with a cold lime-soda ash softening process to control Ca, Mg, and silica followed by clarification, filtration through dual sand-anthracite media, and pH adjustment. Sludge is added to the ash treatment process, and water is returned to the cooling system. (Cassar-FRC)

SHAKING DOWN A SOLIDS HANDLING SYSTEM,
Greater Lawrence Sanitary District, North Andover, MA.
E. Teittinen.
Water/Engineering and Management, Vol 129, No 1, p 45-46, January, 1982. 2 Fig.

Descriptors: *Wastewater facilities *Sludge solids, Treatment plants, *Water treatment facilities, Filters, Pumps, Clogging, Springs, Fibers, Industrial wastes, Textile mill wastes, Waste disposal, Solid wastes.

Problems which occurred during the start-up of a solids handling system in North Andover, Massachusetts are reviewed. Early problems were noted in the development of the vacuum filter operation; these were overcome. At the start, running the vacuum filters with only a primary sludge feed was trouble-free. This ended when activated sludge was generated and mixed with primary. The system's ability to keep pace with the solids being produced became severely limited, and an intensive diagnostic program was begun. Problems were identified in the spring gap and sprays, following which steps had to be taken to ensure that coil integrity would be maintained after they were refurbished. A final refinement in the vacuum filter operation was achieved when ferric chloride and lime were replaced with polymers as dewatering aids. Material handling had been simplified by converting an unused sodium hypochlorite storage tank to bulk polymer storage. In addition to labor savings, significant reductions were realized in processing chemical costs. While there was no reduction in cake solids content due to the conversion, there was a significant increase in volatile solids (65-75%) and a reduction in ash volume for disposal. (Baker-FRC)

DISSOLVED OXYGEN CONTENT MONITORING USING GAS PHASE OXYGEN ANALYSIS IN A HIGH PURITY OXYGEN ACTIVATED SLUDGE PLANT,
Yokohama Sewerage Bureau, Kawasaki (Japan).
Y. Kurokawa, Y. Nameda, Y. Itoh, T. Katoh, and R. Tanuma.
Water Science and Technology, Vol 13, No 9, p 293-298, 1981. 3 Fig, 3 Ref.

Descriptors: *Activated sludge process, *Oxygenation, *Monitoring, Dissolved oxygen, Wastewater treatment, Oxygen transfer, Aeration, *Kawasaki, *Japan.

Dissolved oxygen control in a high purity oxygen activated sludge plant was achieved by monitoring the partial oxygen pressure in the vapor phase and the water temperature. Values calculated from this procedure compared well with measured dissolved oxygen concentrations from April 17 to December 30 at the 1500 cu m per day Ikuta sewage treatment plant, Kawasaki, Japan. A dissolved oxygen rate of 20 mg per liter was found suitable for this plant. Further increases in dissolved oxygen levels did not consistently improve treated water quality. (Cassar-FRC)

A TREATMENT SYSTEM FOR AN ORGANIC CHEMICALS PLANT,
Allied Chemical Company, Danville, IL.
N. L. Lanter, and D. L. Hatfield.
Industrial Wastes, Vol 27, No 6, p 22-23, November/December, 1981. 1 Fig, 1 Tab.

Descriptors: *Chemical wastewater, *Organic compounds, *Chlorinated hydrocarbons, *Wastewater treatment, *Industrial wastewater, Carbon tetrachloride, Acidic water, Sodium hypochlorite, Sedimentation, Chemical wastewater.

The Allied Chemical Company plant at Danville, Illinois, treats six wastewater streams individually before combining them for suspended solids removal and discharge into the city sewer system. The basic process involves reaction of carbon tetrachloride with hydrofluoric acid, using the additional raw materials sulfuric acid, hydrochloric acid, hydrocarbons, finishing agents, sodium hydroxide, and heavy metals. The six wastewater streams are as follows: (1) weak sodium hypochlorite solution, (2) chlorocarbons and chlorofluorocarbons, (3) acidic water containing fluorocarbons, (4) colling tower and boiler blowdown, and (5) and (6) acidic water with up to 50% total suspended solids. Sanitary waste and stream (4) are discharged directly into the sewer. Noncontaminated storm water is transported off-site. Stream (1) treatment catalytically decomposes sodium hypochlorite into oxygen and chloride. Stream (2) treatment involves settling chlorocarbons and separation in a tank; Stream (3) is sent directly to the combined final treatment. The high solids (5) and (6) wastewaters are subjected to sedimentation in the containment vessels. Terminal combined treatment consists of two sedimentation steps and filtration followed by discharge into the sewer. (Cassar-FRC)

AMERICAN HOECHST UPGRADES A TREATMENT SYSTEM THROUGH AUTOMATION,
American Hoechst Corp., Leominister, MA.
V. M. DiTaranto, Jr.
Industrial Wastes, Vol 27, No 6, p 28, 31-33, November/December, 1981. 2 Fig, 2 Tab.

Descriptors: *Heavy metals, *Metal-finishing wastes, *Automation, *Sludge drying, *Wastewater treatment, Nickel, Copper, Zinc, American Hoechst Corporation, Industrial wastewater, Chemical wastewater, Electroplating.

Pretreatment of electroplating wastewater removes 96% total suspended solids, 97% nickel, and 98% zinc at the American Hoechst plastics manufacturing facility at Leominster, Massachusetts. The effluent is then combined with wastewater from the styrene polymerization process for further treatment. The system uses lime neutralization, ferric sulfate coagulation, flocculation, sedimentation, sludge dewatering, and effluent polishing. Influent and effluent metal levels (in mg per liter) average: Cu, 17.2 and 0.9; Ni, 19.2 and 2.4; and Zn, 56.4 and 1.3. Much of the system is automatically controlled, including start-up and shutdown, level control, pH control, sludge centrifugation, and monitoring. (Cassar-FRC)

OPERATIONAL PERFORMANCE OF AN RBC UNIT IN CONJUNCTION WITH A SEPTIC TANK,
British Columbia Univ., Vancouver. Dept. of Civil Engineering.
J. W. Atwater, and G. Bradshaw.
Canadian Journal of Civil Engineering, Vol 8, No 4, p 477-483, December, 1981. 7 Fig, 11 Ref.

Descriptors: *Septic tanks, *Solids contact processes, *Primary wastewater treatment, Wastewater treatment, Rotating biological contactors, Biological treatment, Performance evaluation, Denitrification, Oxidation, Nitrogen removal, *British Columbia.

Data collected from the wastewater system operation at a 60-man prison camp near Agassiz, British Columbia, was analyzed. The system consisted of a rotating biological contactor in series with a septic tank for primary solids removal and sludge storage. A secondary clarifier sent sludge back to the septic tank for recycling. Chlorination and three days of lagooning were followed by discharge of effluent into a stream. An initial odor problem was solved by recycling effluent from the last stage of the contactor back to the septic tank. This system produced an effluent acceptable by federal guidelines, 20 mg per liter for BOD and 25 mg per liter for suspended solids. Effluent quality degenerated if solids were not removed from the septic tank within 12 months. Data suggest that the required surface area for rotating biological contactors operating with primary treatment by septic tanks is three times that using conventional primary treatment. Denitrification occurred concurrently with carbonaceous oxidation. (Cassar-FRC)

AQUACULTURAL APPROACHES TO RECYCLING OF DISSOLVED NUTRIENTS IN SECONDARILY TREATED DOMESTIC WASTEWATER--IV. CONCLUSIONS, DESIGN AND OPERATIONAL CONSIDERATIONS FOR ARTIFICIAL FOOD CHAINS,
California Univ., Davis. Dept. of Biology.
M. S. Gordon, D. J. Chapman, L. Y. Kawasaki, E. Tarifeno-Silva, and D. P. Yu.
Water Research, Vol 16, No 1, p 67-71, January, 1982. 10 Ref.

Descriptors: *Aquaculture, *Tertiary wastewater treatment, Wastewater treatment, *Recycling, *Nutrients, Design criteria, Heavy metals, Metals, *Food chains, Fate of pollutants, Effluents, Bioaccumulation, Accumulation, Nutrient removal, Cultures, Algal growth, Algae, Scenedesmus, Cladocerans, Crustaceans, Fish, Daphnia, Chlorophyta, Shinrs, Fathead minnows, Carp.

This paper summarizes the results of three previous papers on growing food chains in secondary wastewater for the purposes of tertiary wastewater treatment in effluent which has been chlorinated, then dechlorinated. The food chains consisted of unicellular green algae, herbivorous cladocerans or fish, and carnivorous fish, followed in som cases by filamentous green algae. Aspects studied in the first three papers were nutrient uptake, biological productivity, and heavy metal accumulation. Some general conclusions are drawn in this paper. This process is feasible for reducing effluent nutrient loading and for growing usable crops of organisms in sunny, temperate regions. Batch cultures are reliable, but continuous cultures are not likely to be usable without pH control. A near-neutral pH will produce high densities of suspended algal cells, while absence of pH control will produce clumped cells for easy harvesting. These aquaculture operations are best suited to rural and suburban areas,

LIBRARY U. OF I.- URBANA CHAMPAIGN

where competition for land use is not too great. (Cassar-FRC)

AQUACULTURAL APPROACHES TO RECYCLING OF DISSOLVED NUTRIENTS IN SECONDARILY TREATED DOMESTIC WASTEWATERS--III. UPTAKE OF DISSOLVED HEAVY METALS BY ARTIFICIAL FOOD CHAINS,
California Univ., Davis. Dept. of Biology.
E. Tarifeno-Silva, L. Y. Kawasaki, D. P. Yu, M. S. Gordon, and D. J. Chapman.
Water Research, Vol 16, No 1, p 59-65, January, 1982. 9 Tab, 23 Ref.

Descriptors: *Aquaculture, *Tertiary wastewater treatment, *Heavy metals, *Accumulation, *Nutrients, Fate of pollutants, *Food chains, Cultures, Wastewater treatment, Metals, *Recycling, Effluents, Bioaccumulation, Algae, Chlorophyta, Scenedesmus, Cladocerans, Daphnia, Fish, Notemigonus, Pimephales, Shiners, Fathead minnows.

Concentrations of 15 heavy metals (Ba, Cd, Co, Cr, Cu, Fe, Mn,Mo,Ni, Pb, Sn, Sr, Ti, V, Zn) accumulating in an algae algae-cladoceran-fish food chain growing in secondary wastewater effluent were reported. The food chain consisted of Scenedesmus (algae); Daphnia magna and Daphnia pulex (cladocerans); and Notemigonus crysoleucas and Pimephales promelas (fish). Concentration factors were higher in algae (500-30,000) than in Daphnia (30-6000) and fish (4-1600). The concentrations of metals found in algal cells depended on buffering and presence of ferrous sulfate. Relative abundances of metals in algae were substantially different from the abundances in effluent. Concentrations of metals in cladocerans were 2 to 50% of those in algal cells. Relative abundance differed between algae and Daphnia and between Daphnia magna and Daphnia pulex. Most elements were either equal in both species or higher in Daphnia magna than in Daphnia pulex. For 7 of 9 metals fish showed lower metal concentrations in muscles than the Daphnia they ate. Relative abundances of the metals differed between the two fish species. (Cassar-FRC)

AQUACULTURAL APPROACHES TO RECYCLING OF DISSOLVED NUTRIENTS IN SECONDARILY TREATED DOMESTIC WASTEWATERS--I. NUTRIENT UPTAKE AND RELEASE BY ARTIFICIAL FOOD CHAINS,
California Univ., Davis. Dept. of Biology.
L. Y. Kawasaki, W. Tarifeno-Silva, D. P. Yu, M. S. Gordon, and D. J. Chapman.
Water Research, Vol 16, No 1, p 37-49, January, 1982. 2 Fig, 8 Tab, 55 Ref.

Descriptors: *Tertiary wastewater treatment, *Nutrient removal, *Recycling, *Aquaculture, Wastewater treatment, Algal growth, Algal harvesting, Fish, Cladocerans, Algae, Chlorophyta, *Food chains, Nitrates, Phosphates, Effluents, Nitrogen removal, Phosphorus removal, Cultures, Scenedesmus, Cladophora, Ulothrix, Daphnia, Notemigonus crysoleucas, Pimephales promelas, Notropis lutrensis, Carp, Shiners, Fathead minnows, *Water reuse.

The nutrient (nitrate and phosphate) dynamics of each stage in artificial food chains was investigated in a secondary wastewater effluent for the purpose of producing a tertiary-treated effluent. Suitable organisms were Scenedesmus, a unicellular green alga; Cladophora and Ulothrix, filamentous green algae; Daphnia magna and Daphnia pulex, cladocerans; and Notemigonus crysoleucas, Pimephales promelas, and Notropis lutrensis, fish. Addition of 1 ppm ferrous iron and 5% carbon dioxide were required to provide good algal growth for the cladocerans' food supply. Nitrate and phosphate removals in buffered algal cultures were 78% and 55%, respectively; in unbuffered algal cultures, 30% and 98%, respectively. The high removal of phosphate in the unbuffered cultures was probably a result of precipitation of phosphate at the high pH levels. The cladocerans and fish returned ammonia and phosphate to the effluent. These were removed in the final stage by filamentous green algae. Continuous light conditions were more conducive to nutrient removal than a 12 hour light-12 hour dark cycle. Daily harvesting rates of 25-75% of culture volumes did not significantly affect nitrate removals in buffered algal cultures, but phosphate removals were inversely proportional to harvesting rates. (Cassar-FRC)

DESTABILIZATION OF BIOLOGICAL SOLIDS WITH FERRIC CHLORIDE,
North Carolina State Univ. at Raleigh. Dept. of Civil Engineering.
A. C. Chao, and T. M. Keinath.
Water Research, Vol 16, No 1, p 23-30, January, 1982. 10 Fig, 1 Tab, 20 Ref.

Descriptors: *Activated sludge process, *Coagulation, *Ferric chloride, Wastewater treatment, Flocculation, Suspended solids, Organic matter, Hydrogen ion concentration, Microorganisms.

A two-step pH control method is given for coagulating suspended biological solids produced during upsets in the activated sludge process. This situation is characterized by high levels of sludge pinpoint flocs and dispersed cells. In ferric chloride coagulation the flocs are readily removed at low dose levels, but the cells, only a small percentage of the total suspended solids, require a much higher dose of coagulant for complete removal. In the two-step method, ferric chloride is added quickly so that solution pH drops to 3-4. During this low pH period the ferric chloride is in soluble form, effectively sorbed by biological particles. After 20 sec mixing, the pH is adjusted to 5.0. Then the soluble ferric chloride species polymerizes, forming insoluble bridges more evenly sorbed by solids than those produced by the constant pH method. This method removed 13 mg per liter biological solids with 1 mg per liter ferric chloride, a 25% savings in chemical over the constant pH method. (Cassar-FRC)

WASTEWATER DECHLORINATION STATE-OF-THE-ART FIELD SURVEY AND PILOT STUDIES,
Los Angeles County Sanitation Districts, Whittier, CA.
C. Chen, and H. B. Gan.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-102336, Price codes: A06 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-169, October 1981. 5 p, 6 Fig. 14-12-150, 68-03-2745.

Descriptors: *Wastewater treatment, *Dechlorination, *Activated carbon, *Sulfur dioxide, *Holding tanks, *Cost analysis, Residual chlorine, Coliforms, Effluents, Aeration, Bacteria, chemical treatment, Disinfection, Los Angeles county, California.

A study of dechlorination was conducted in the County Sanitation Districts of Los Angeles County to determine the utility and efficiency of the sulfur dioxide method and to provide a cost-effective comparison of sulfur dioxide and two other methods of dechlorination, namely, activated carbon and holding tank processes. Pilot-scale testing indicated that no degradation of physical and chemical water quality occurred in the dechlorinated effluents from any of the three dechlorination processes investigated. However, a one to two order of magnitude increase in total coliform density in the 10-minute samples following cechlorination was commonly observed among the three dechlorination processes. The increase seemed to originate from contamination by the existing microorganism communities in the dechlorinated effluent rather than from the reactivation of injured bacterial cells. A field survey involved the canvassing of 55 operating plants in California by mail, telephone, and site visits to selected facilities. The feed forward method of sulfur dioxide dosage control with signals received from both a flow and residual chlorine controller appeared to be the most commonly employed method. Although overdosing of sulfur dioxide was frequently necessary to meet the residual chlorine discharge standards, most installations found pH adjustment and reaeration of the dechlorinated effluent unnecessary. Process cost estimates based on the field survey and pilot-plant study have been prepared for all three dechlorination processes. The sulfur dioxide process seems to be the most cost-effective method for dechlorination. (Moore-SRC)

Descriptors: *Wastewater treatment, *Activated sludge process, *Effluents, *Statistical analysis, Standards, Variability, Reliability, Mathematical models, Biochemical oxygen demand, Suspended solids, Effluent variables.

Variations in the daily effluent quality of 43 activated sludge processes were examined. From an analysis of the data, it was found that the effluent variables are not distributed symmetrically, and generally their distributions are skewed further to the right than to the left of the most frequent value. The log-normal distribution was fond to fit the observed effluent biochemical oxygen demand (BOD) and suspended solids (SS) data most consistently. Using the lognormal distribution and a coefficient of reliability (COR), a probabilistic model and design tables and graphs have been developed for predicting achievable effluent BOD and SS concentrations. Mean constituent values are correlated to selected standards with the COR. The proposed model can be used in the design of a treatment process expected to perform at a certain reliability and/or to estimate the reliability of an operating treatment plant. Validity of the reliability model in prediction of effluent quality performance has been verified. The standard deviation was found to be the most appropriate indicator of stability. A standard deviation of 10 g/cu m was selected as stability cut-off point on the basis of a qualitative examination of the data. Plants with effluent values below 10 g/cu m are considered stable; plants with values greater than 10 g/cu m are considered unstable. No single variable or group of variables was found that could be used to characterize the variability of effluent quality for all plants in general. The appropriateness of effluent standards as they are currently stated was discussed, and the use of the geometric mean as a measure of central tendency of daily effluent quality data was recommended for setting discharge standards. SURVEY AND EVALUATION OF FINE BUBBLE DOME DIFFUSER AERATION EQUIPMENT,
Association of Metroplitan Sewerage Agencies, Washington, DC.
D. H. Houck, and A. G. Boon.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-105578, Price codes: A09 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-222, October, 1981. 8 p, 5 Tab. R806990.

Descriptors: *Aerators, *Wastewater treatment, *Oxygen transfer, *Activated sludge process, Maintenance, Cost analysis, Energy, Design criteria.

Aeration equipment employed in activated sludge service is usually the single largest energy consumer in a wastewater treatment plant. Because fine bubble aeration equipment has the potential for markedly higher oxygen transfer efficiencies than coarse bubble designs, its use is rapidly expanding in new or retrofitted treatment plants. In order to assess the long-term oxygen transfer performance, and operation and maintenance history of fine bubble dome diffuser aerators, 19 treatment plants were studied. Thirteen of the plants were in the United Kingdom, two in the Netherlands, and four in the U. S. As nearly as possible, data on influent and effluent wastewater characteristics, power demand, air supply, and process parameters were compiled for a 5-yr period. Maintenance personnel were interviewed to develop a summary of long-term operation and maintenance experience. Specific designs and plant equipment for aeration, air clearing, and diffuser maintenance were studied. Although this survey clearly shows the need for optimized design and operating control strategies to realize the full energy saving potential of this type of equipment, dome diffuser fine bubble aeration systems were providing relatively efficient, low-maintenance service in the plants visited. DEMONSTRATION PHYSICAL CHEMICAL SEWAGE TREATMENT PLANT UTILIZING BIOLOGICAL NITRIFICATION,
Municipal Environmental Research Lab., Cincinnati, OH.
J. F. Kreissl, and R. F. Lewis.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-101643, Price codes: A05 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-173, October, 1981. 7 p, 2 Fig, 2 Tab.

Descriptors: *Physicochemical treatment, *Biological wastewater treatment, *Nitrification, *Wastewater treatment, Domestic wastes, Phosphorus removal, Nitrogen removal, Effluent, Oxygen demand.

This demonstration project was conducted to show that wastewater could be treated in a physical-chemical wastewater treatment plant employing a biological intermediate stage for oxidation of nitrogenous material to produce a high quality effluent and provide different treatment levels to meet a variety of effluent requirements. The physical-chemical plant chosen was of a modular design employing high-rate processes which normally facilitate a relatively speedy installation, a minimum amount of lag time to produce the desired effluent quality, and ease of transport for relocation to other critical areas when needed. The plant was located in the drainage area of a planned residential development known as Beechgrove Village in Kentucky. The wastewater was domestic in nature with no commercial or industrial sources. The removals of BOD5, COD, total organic carbon and suspended solids were excellent. Phosphorus removal was also excellent but the nitrogen removal was rather low. Nitrification never properly developed during the course of the study, even though the nitrogen removals averaged 32%. Although the system produced a consistent, high quality effluent, its utility as a transportable system was only partially demonstrated and its viability as a treatment sequence could not be confirmed due to several design and operational problems. DESIGN OPTIMIZATION OF THE CHLORINATION PROCESS: VOLUME 1. COMPARISON OF OPTIMIZED PILOT SYSTEM WITH EXISTING FULL-SCALE SYSTEMS,
California Dept. of Health Services, Berkeley.
E. Sepp, and P. Bao.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-100835, Price codes: A07 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-167, October, 1981. 5 p, 2 Fig, 2 Tab. S-803459.

Descriptors: *Chlorination, *Wastewater treatment, *Disinfection, *Effluents, *Residual chlorine, Coliforms, Toxicity, Pilot plants, Contact time, Mixing, Plug flow, Bacteria, Water pollution control.

Parallel wastewater effluent chlorination studies were done on a mobile optimized chlorination pilot system and the full-scale system at eight different treatment plants. Disinfection efficiency was measured by total coliform enumeration and chlorine residual tests. Parallel flow-through fish bioassays were also conducted at each location. The objectives of the study were as follows: achievement of adequate disinfection with minimum use of chlorine; reduction of chlorine-induced toxicity; and writing of a design manual. At 7 of the 8 plants studied the optimized pilot plant achieved an equivalent level of disinfection with significantly lower chlorine dosage, in some cases more than 50% lower, than the full-scale plants. The pilot plant chlorine residuals were also lower by the same proportions. The reasons for the better pilot plant results were rapid initial mixing, improved chlorine control, and plug flow contact. In most cases the bacterial survival ratio could be expressed as a function of the product of chlorine residual and contact time. There appeared to be, however, a limiting contact time to which this relationship applied. The degree of coliform reduction obtained during initial mixing appeared to be a function of chlorine residual. (Author's abstract)

HOURLY DIURNAL FLOW VARIATIONS IN PUBLICLY-OWNED WASTEWATER TREATMENT FACILITIES,
Weston (Roy F.), Inc., West Chester, PA.
W. H. Chesner, and M. Pai.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-107954, Price codes: A06 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-218, October, 1981. 4 p, 2 Tab. 68-03-2775.

Descriptors: *Flow rate, *Wastewater, *Sewer systems, *Wastewater facilities, *Sewer infiltration, Pumps, Seasonal distribution, Industrial wastewater, *Diurnal distribution, Groundwater level, Design criteria, *Hydraulic design.

Flow variations are rarely addressed in the design of wastewater treatment plants. A survey of 39 sanitary sewer collection systems was undertaken to determine the magnitude of hourly peak flows and to identify the collection system parameters that were most influential in affecting the observed peaks. Significant collection system parameters identified included industrial contribution, average age of the collection system, depth to groundwater, and low-lift, pre-plant pumping stations. Collection systems with industrial or institutional flow contributions greater than 40% were found consistently to have higher daily peak flows than those below 40%. Industrial flows can also be seasonal, with flows during the industrial season resulting in higher peaking factors. Peak flow hours of the day tend to occur at earlier hours in industry-dominated systems. Nonindustrial collection systems with an average age greater than 25 years and high groundwater tables are more susceptible to infiltration, and exhibit higher peaking factors during the spring or infiltration season. The mean average hourly peak flow for nonindustrial systems, excluding inflow, was found to be 1.23 times the annual average daily flow. As collection system flow rate increases, variations around the mean value decrease. Instantaneous maximum peaking factors for low-lit, pump-dominated systems ranged from 1.3 to 4.7, and the minimum instantaneous flow factors varied from 0 to 0.8. (Moore-SRC)

EVALUATION OF ON-SITE WASTEWATER TREATMENT AND DISPOSAL OPTIONS,
Municipal Environmental Research Lab., Cincinnati, OH.
J. A. Heidman, and R. P. G. Bowker.
Available from National Technical Information Service, Springfield, VA 22161 as PB82-101635, Price codes: A11 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-178, October, 1981. 5 p,1 Tab. 68-03-2627.

Descriptors: *Wastewater treatment, *Wastewater disposal, *Domestic wastes, *On-site systems, *Wastewater management, Literature review, Disinfection, Land disposal, Biological treatment, Physicochemical treatment, Cost analysis, Environmental effects, Soil properties.

A literature review of published and unpublished data was conducted to identify conceivable on-site systems, including wastewater manipulation, treatment, and disposal options. Wastewater manipulation options included flow reduction, wasteload reduction, and waste segregation. Treatment options included disinfection and biological and phyical/chemical methods. Disposal options included air, soil, and surface water methods and practical combinations. Both tested and untested systems were identified, and combinations of the various components were developed. An equipment inventory was then performed to determine the availability of hardware for the systems, and system components were identified. Data on engineering, economic, and environmental acceptability characteristics were collected. These systems were evaluated on the basis of performance, operation and maintenance, environmental acceptability, and total annual cost for 15 specific site conditions. Site conditions were defined by soil percolation rate, soil depth, slope, available land area, direct discharge effluent requirements, and net evaporation. Where site conditions are appropriate (conventional septic tank-soil absorption systems) were found to be the least-cost and top-ranked method of on-site wastewater treatment and disposal. Under other conditions, systems incorporating other methods of disposal, such as soil disposal with modified distribution, mounds, evapotranspiration, irrigation, evaporation, or direct discharge, are appropriate. A septic tank normally provides adequate pretreatment for most of these disposal methods. Where irrigation or surface discharge disposal is used, additional treatment, such as that provided by an intermittent sand filter and iodine disinfection, may be required. Use of low pressure membrane filtration where high quality effluent is required also appears promising, based on very limited operating experience.

PRODUCTION ENGINEERING AND MARKETING ANALYSIS OF THE ROTATING DISK EVAPORATOR,
Municipal Environmental Research Lab., Cincinnati, OH.
J. A. Heidman, and R. P. G. Bowker.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-101676, Price codes: A04 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-179, October, 1981. 4 p, 1 Fig, 5 Tab. 68-03-2738.

Descriptors: *Wastewater treatment, *On-site systems, *Rotating disk evaporators, *Cost analysis, *Domestic wastes, *Marketing, Climates, Evaporators, Economic aspects, Wastewater disposal.

Recent research into the on-site, mechanical evaporation of wastewater from single family homes revealed that a rotating disk evaporator (RDE) could function in an non-discharging mode. Such a device has potential use where site limitations preclude conventional methods for on-site disposal. A marketing analysis of the RDE defined the market potential, developed a practical design, estimated production and installation costs, and refined market estimates based on cost comparisons. A small unit suitable for only the most favorable climates would have an FOB factory selling price of about $10,000 if fabricated with aluminum disks. Distribution costs and freight will amount to about $3,300. An additional $8,000 is required for installation (including a storage tank), resulting in a total capital cost of about $22,000. Including amortized capital costs, and operating and maintenance costs, an RDE system would treat household wastewater for about 3.4 cents/gallon. Because of these high

LIBRARY U. OF I.- URBANA-CHAMPAIGN

costs, the potential RDE market is quite small. It is limited to very expensive homes, second homes with no winter occupancy, and high cash-flow, low sewage-flow commercial establishments. Furthermore, unfavorable climatic conditions eliminate much of the nation from consideration. It is unlikely that manufacturers of RDE systems would collectively generate national sales of 100 units/year. (Moore-SRC)

TREATABILITY STUDIES OF PESTICIDE MANUFACTURING WASTEWATERS,
Research Triangle Inst., Research Triangle Park, NC.
R. Zweidinger, E. Monnig, L. Little, R. Batten, and D. Liverman.
Environmental Protection Agency Project Summary EPA-600/S2-80-077, December, 1981. 4 p, 1 Fig, 3 Ref.

Descriptors: *Pesticides, *Industrial wastes, *Wastewater treatment, *Biological wastewater treatment, Activated sludge process, Fungicides, Herbicides, Insecticides, Carbamate pesticides, Biodegradation, Nitrification.

Laboratory and pilot studies of the treatability of pesticide manufacturing wastewaters were conducted in a project designed to investigate the suitability of individual pesticide manufacturing wastewaters for discharge to biological treatment systems, whether publicly owned treatment works or on-site systems. The pesticides studied were carbaryl, dinoseb, atrazine, dazomet, glyphosate, and an ethylenebisdithiocarbamate fungicide. The approach taken with each pesticide manufacturing wastewater was prioritized; that is, less costly, more available methods of treatment were investigated. The preferred method of treatment was assumed to be biological. Both carbaryl manufacturing wastewater, when mixed 1 part in 9 with muicipal wastewater, and carbaryl itself, spiked at 10 mg/l in municipal wastewater, appear suitable for biological treatment by acclimated systems if additional provision is made for removing ammonia in the effluents from the treatment system. The effluent from the manufacture of dinoseb and atrazine proved suitable for a treatment system involving preliminary activated carbon filtration to remove the herbicide, followed by biological treatment to reduce oxygen demand exerted by solvents and other organic compounds. It is recommended that dazomet wastewater be diluted to at least 1:1000 in municipal wastewater to minimize the negative effects on the nitrification of during the activated sludge treatment process. Biological treatment significantly reduced the toxicity of hlyphosate effluents, but hlyphosate itself showed only partial reduction with treatment (38 to 45%). The presence of ethylenebisdithiocarbamate fungicide manufacturing wastewater strongly inhibits nitrification in activated sludge units. Biological treatment decreased, but failed to eliminate, the amount of ethylenethiourea in the wastewaters. (Moore-SRC)

TREATMENT OF SULFITE EVAPORATION CONDENSATE WITH AN ANAEROBIC REACTOR,
Washington Univ., Seattle. Dept. of Civil Engineering.
M. M. Benjamin, J. F. Ferguson, and M. E. Buggins.
In: Proceedings TAPPI Environmental Conference, 1981, TAPPI Press, Atlanta, Georgia, p 307-316. 6 Fig, 7 Tab, 7 Ref.

Descriptors: *Anaerobic treatment, Methane fermentation, Sulfite evaporator condensate, *Wastewater treatment, *Organic wastes, Sulfur compounds, Toxicity.

A study has been underway since 1979 evaluating the use of submerged anaerobic reactors to treat sulfite evaporator condensate (SEC). Both SEC from a calcium bisulfite mill and a synthetic SEC have been treated at an organic loading of 16 kg COD/m3.d and a detention time of seven hours, achieving 79% to 90% reduction in COD. A yield coefficient of 0.09 gr cells/gr COD removed has been calculated, and the balance of the removed COD is stoichiometrically converted to CH4. Toxicity from sulfur compounds, furfural or trace organics have not been a problem. Partial neutralization of the feed is necessary, as are additions of nitrogen, phosphorus and some trace nutrients. The process produces methane with a significant energy value. In addition, when used as pretreatment, it reduces the energy needed for aerobic treatment.

DEVELOPING AN EFFECTIVE MAINTENANCE PROGRAM PART A: EVALUATION,
Morris Forman Wastewater Treatment Plant, Louisville, KY.
G. R. Freiberg, and W. B. Thompson.
Water/Engineering and Management, Vol 129, No 1, p 30-33, January, 1980. 4 Fig.

Descriptors: *Maintenance, *Wastewater treatment facilities, Maintenance costs, Water treatment facilities, Planning, Management, *Louisville, Kentucky.

Many wastewater treatment facilities have a common problem of spending too much time keeping things running, and not enough time searching for ways to improve operational efficiency. The wastewater treatment plant in Louisville, Kentucky was used to develop an evaluation and implementation procedure for the establishment or upgrading of maintenance systems. The focus of the study was primarily on preventive maintenance, but water and wastewater managers and engineers should find the approach applicable to most maintenance activities. The strengths and weaknesses of each functional area were examined. One major problem which was exposed by this procedure was a substantial spread between estimated and actual costs. Reasons for this appeared to be that either the work was improperly estimated, or workers took too much time and used too much material to complete the task. A review of the existing work order procedure led to a new, more clearly defined set of instructions. Corrective and major maintenance scheduling and planning procedures proved to be ineffective. District-wide accounting and spare parts inventory procedures were included in the study because of their indirect, but critical, effect on the entire maintenance program. The purpose of any maintenance management system is to obtain reliable, efficient, cost-effective service from the equipment. Preventive maintenance is seen as just one element of any comprehensive program. (Baker-FRC)

TERMINAL REACTIONS IN THE ANAEROBIC DIGESTION OF ANIMAL WASTE,
Research Council of Alberta, Edmonton.
D. R. Boone.
Applied and Environmental Microbiology, Vol 43, No 1, p 57-64, 1982. 3 Fig, 3 Tab, 21 Ref.

Descriptors: *Anaerobic digestion, *Animal wastes, Organic matter, Biological treatment, *Wastewater treatment, Digestion, Biodegradation.

The terminal reactions of anaerobic digestion were examined to determine whether they are rate limiting. Acetate degradation was measured in digestors which were fed animal waste and in digestors fed animal waste with ultimate methanogenic substrates added continuously to the fermentation. The continuous pumping of acetic acid into the digestor caused an increase in acetate concentration in the effluent which was proportional to the increase in total acetate production, biological production plus amount pumped in. Propionate concentration also increased, perhaps due to product inhibition of propionate-degrading bacteria by the higher levels of acetic acid or due to increased propionate production by fermentative bacteria. When H2/CO2 was the added substrate, there were occasional instabilities in the fermentation immediately after increases in addition rate. The data allow the hypothesis that abrupt changes in digestor influent substrates, which cause a rapid increase in hydrogen production by hydrogen-producing microflora, could create instabilities, causing digestor failure. Digestors with added acetate or H2/CO2 converted at least 95% of the added substrates stoichiometrically to methane, assuming gas production from the animal waste was the same as in controls with no added substrates. Also, volatile solids destruction was similar in the presence and absence of added substrates, suggesting that fermentation of animal waste was not significantly affected by the added load on the methanogenic bacteria. Acetate levels in the digestor with added H2/CO2 were higher, apparently due to both increased acetate production and inhibition of acetate dissimilation. Increases in H2 addition caused temporary instabilities in the fermentation, whereas increases in acetate addition did not. (Baker-FRC)

BIODEGRADATION OF GLYCIDOL AND GLYCIDYL NITRATE,
Army Natick Research and Development Labs., MA.
D. L. Kaplan, J. H. Cornell, and A. M. Kaplan.
Applied and Environmental Microbiology, Vol 43, No 1, p 144-150, 1982. 7 Fig, 13 Ref.

Descriptors: *Nitrates, *Biodegradation, *Organic compounds, *Wastewater treatment, Chemical reactions, Industrial wastes, Biological treatment, Biological wastewater treatment, Nitroglycerine, Mutagens, *Glycidol.

The fate of glycidol and glycidyl nitrate was examined under exposure to microbial activity in order to indicate the feasibility of a biological approach to the decomposition of glycerol trinitrate chemical reaction products. The desensitization of glycerol trinitrate containing waste streams with calcium hydroxide produces the expoxides, glycidol and glycidyl nitrate. Epoxide rings of both compounds are unstable to heat in aqueous solutions. They open to form glycerol 1-mononitrate and presumably glycerol. Microbial activity accelerates these transformations. Glycerol 1-mononitrate was slowly denitrated to form glycerol. Glycidol and glycidyl nitrate caused base pair substitutions in the Ames test for mutagenicity, whereas glycerol 1-mononitrate tests were negative. Biological treatment causes a loss of the mutagenic activity. (Baker-FRC)

THE FATE OF SOLUBLE, RECALCITRANT, AND ADSORBING COMPOUNDS IN ACTIVATED SLUDGE PLANTS,
Henkel KGaA, Dusseldorf (Germany, F.C.). Dept. of Ecology.
P. Wierich, and P. Gerike.
Ecotoxicology and Environmental Safety, Vol 5, No 2, p 161-170, 1981. 3 Fig, 1 Tab, 5 Ref.

Descriptors: *Wastewater treatment, *Adsorption, *Activated sludge process, *Fate of pollutants, Organic compounds, Degradation, Biodegradation, Model studies, Retention time.

A mathematical model was developed to describe the fate of a compound in the activated sludge stage of sewage treatment plants. The compounds under consideration were soluble, nonbiodegradable, and strongly adsorbing. It was concluded that high adsorption in a batch test did not guarantee efficient elimination in a continuous flow activatd sludge process. The effluent concentration reached a limiting value dependent on adsorption constant of the sludge and the surplus sludge wasteage rate. The retention time of the adsorbate exceeded the mean retention time of the sewage and increased with increasing adsorption constant. The maximum

load of the adsorbent on the sludge was lower than the maximum capacity indicated by static batch tests, but it was higher than the influent concentration. The model described in this paper permitted calculation of a base value above which elimination in activated sludge tests was due to biodegradation and not just adsorption. (Cassar-FRC)

MUNICIPAL SEWAGE TREATMENT - SOME RECENT DEVELOPMENTS,
J. M. Sidwick.
Effluent and Water Treatment Journal, Vol 21, No 11, p 501, 503, 505-507, November, 1981. 1 Fig, 1 Tab, 16 Ref.

Descriptors: *Municipal wastewater, *Wastewater treatment, Reviews, Sedimentation, Filtration, Activated sludge process, Nitrification, Dissolved oxygen, Anaerobic conditions, Aeronic conditions, Anaerobic digestion, Computers, Automation, *Wastewater management.

Recent developments in the municipal sewage treatment field are discussed. The two most significant trends in primary sedimentation are the increasing use of chemical precipitation and a move toward reducing retention time. Chemical precipitation is being used primarily to remove phosphorus from sewage. Biological filtration has recently been connected with serious odor complications. Part of the problem seems to be the inability of a high rate filter to supply sufficient oxygen to maintain an adequately aerobic biomass, with the consequent development of anaerobic degradation products which escape from the filter aerially or with the wasted sludge. In the conventional activated sludge system the most important new developments relate to the use of this process for nitrogen removal. The chief attraction of biological denitrification is that the nitrogen is completely removed from the system as nitrogen gas without causing atmospheric pollution or a liquor concentrate. Two of the most important recent developments from conventional activated sludge treatment are the use of oxygen-enriched air and the deep shaft process. Biological fluidized beds have only very recently been considered for wastewater treatment. The principle of the fluidized beds is that mixed microbial cultures associated with wastewater have excellent adhesion characteristics. The value of anaerobic treatment has been appreciated for many years, but its application has largely been restricted to sludges and a few particularly strong biodegradable organic industrial effluents. The long retention periods needed for this process have tended to make it costly, and effluents have not been of high quality. Recent advances in the area of instrumentation for automation and control are briefly mentioned. (Baker-FRC)

LABORATORY EXPERIMENTS ON THE PHYSICO-CHEMICAL TREATMENT OF MEAT PROCESSING EFFLUENTS,
Research Inst. for Water Resources Development, Budapest (Hungary).
I. Tookos.
Effluent and Water Treatment Journal, Vol 21, No 11, p 493-500, November, 1981. 6 Fig, 3 Tab, 29 Ref.

Descriptors: *Meat processing industry, *Wastewater treatment, Effluents, Industrial wastes, Chemical coagulation, Separation techniques, Particle size, Colloids, Dissolved organic matter, Chemical engineering, Reviews, Bentonite, *Chemical treatment.

Effluents produced in the course of meat processing operations are highly detrimental, rich in coarse, floating, suspended and dissolved organic pollutants, and have high oxygen demands and unpleasant odors. Intensive mechanical primary treatment processes are effective in removing only coarse pollutants larger than 1-2 mm diameter, but the effluent is still very highly polluted. The physico-chemical treatment of wastewaters produced during the slaughtering and processing of poultry and meat is reviewed. The amount of pollutants removed was found to increase in a linear proportion with the strength of the wastewater treated. A relatively constant treatment efficiency can be expected. Evidently, the same close correlation exists between the raw wastewater and the treated effluent as well. In the case of wastewaters containing particulate matter not larger than 1-2 mm in size, laboratory studies demonstrated that the amount of colloidal substance precipitated did not depend on whether the pollutant was present in suspended form, or in a state which may be regarded as dissolved from the viewpoint of treatment technology. The optimal range of chemical feed rate determined by the laboratory provided no more than preliminary guidance. Higher feed rates may be needed in the interests of precipitate separation if the stability of the resulting sludge is poor. Bentonites alone were ineffective in precipitating colloidal proteins. Results obtained with sulfonic acid were poorer than had been expected. This was due to the carbohydrate content of the coagulant used in the study. The precipitate formed was highly unstable and impossible to remove by sedimentation. (Baker-FRC)

Detailed information concerning the biochemical characteristics of microbial populations employed in anaerobic digestion aid in optimization of the processes. Studies were performed on laboratory methane digesters treating food processing wastewaters, using recently developed techniques for isolating and growing strictly anaerobic bacteria. The pilot-scale digester was originally inoculated with municipal digester sludge. Media used for enumeration of the total flora and the lactate, propionate and acetate utilizing flora included an all-synthetic reference medium, a rumen fluid medium, a medium based on digester fluid, a medium based on the fluid from the digester from which the flora was taken, and fluid from a municipal digester. The anaerobic precautions employed were adequate to protect the oxygen-sensitive organisms. The predominant bacteria in the total flora were slow growing. The all-synthetic medium seemed to be the medium of choice for total flora enumeration. Presumptive identification was made of the lactate-utilizing strains, the presence of which indicates that the digestion of sugars proceeds through a lactate phase. Acetate enrichment cultures were set up to ascertain the importance of acetate as an intermediate in sugar digestion under the test conditions. After six transfers, bacteria of two principal morphological types were demonstrated: an elongated filament and a sarcina, which were tentatively identified with recently described strains. In propionate enrichment cultures, after four transfers, consumption of propionate and formation of methane were noted. Microscopic observation at this stage revealed the presence of a filamentous bacterium analogous to that obtained on acetate enrichment. Previous studies have shown that degradation of acetate and propionate does not take place in the presence of hydrogen. Hydrogen is therefore being efficiently eliminated from this medium by the methanogenic bacteria. (Carroll-FRC)

INCREASING WASTEWATER TREATMENT EFFICIENCY (UBER DIE ERHOHUNG DES WIRKUNGSGRADES DER ABWASSERREINIGUNG),
P. Benedek.
GWF-Wasser/Abwasser, Vol 122, No 12, p 572-581, 1981. 6 Fig, 10 Tab, 37 Ref. English Summary.

Descriptors: *Wastewater treatment, *Activated sludge process, *Cost effectiveness, Activated carbon, Lake Balaton, *Hungary, Chemical coagulation, Aluminum sulfate, Phosphorus removal, Heavy metals, Organic compounds, Sand filtration, Technology.

In recent years VITUKI, the central research institute of the Hungarian water agency, performed laboratory, pilot and full-scale studies on improvements in wastewater treatment technology. Operating data, cost analyses, and the possibility of process combinations are reported. Heavy metal removal following filtration was found to be poorer in biologically treated wastewater than in the raw wastewater, apparently due to complexation by degradation products. Therefore maximal heavy metal removal prior to biological treatment is important. Providing a mixing pond, prior to the preclarifier, in which the wastewater remains for a few minutes in contact with raw sludge recycled from the preclarifier at the rate of 10-20% would allow precipitation of metals by the sulfides present in the raw sludge. Addition of powdered activated carbon during the activated sludge process was shown to enhance refractory organics removal. Phosphorus elimination, especially important in the case of the Lake Balaton water supply, was accomplished by addition of iron or aluminum sulfate, or with a combination of activated bentonite, aluminum sulfate and polyelectrolytes. Sand filtration guidelines are currently being optimized. Cost comparisons for different combinations of treatment processes showed that the activated sludge process with activated carbon provides greatest cost effectiveness for small and medium sized wastewater treatment plants and can easily be combined with phosphate precipitation by aluminum sulfate. THE IMPORTANCE OF THE SOLIDS CONTENT OF THE SLUDGE IN ANAEROBIC ALKALINE DIGESTION (DIE BEDEUTUNG DES FESTSTOFFGEHALTS BEI DER SCHLAMMFAULUNG),
Stuttgart Univ. (Germany, F.R.). Inst. fuer Siedlungswasserbau, Wassergueteund Abfallwirtschaft.
H. Kapp.
Wasserwirtschaft, Vol 71, No 11, p 319-322, 1981. 3 Fig, 6 Ref. English Summary.

Descriptors: *Mathematical studies, *Anaerobic digestion, *Wastewater treatment, Organic compounds, Sewage gas, Energy conservation, Sludge solids.

Anaerobic digestion has the advantages over aerobic digestion for sewage treatment of lower energy costs (the air supply accounts for 80% of the total energy requirement in an aerobic sewage treatment plant) and production of an off gas usable for heating. Disadvantages include the lability of the process and greater construction costs. A simple equation was developed for assessing the degree of degradation of the organic matter and thus the degree of anaerobic stabilization. Degradation rates of about 50% based on the organic matter supplied are considered normal for municipal sludges. The degree of sludge degradation was plotted against the loss on ignition of the original sludge, using the loss on ignition in the digester sludge as the parameter. This equation and graph should be used for evaluating the digestion results only over long periods (e.g., months), although this is also customary for other methods as well (solids balances). The method is applicable for operation with or without water withdrawal. A pseudo-three-dimensional plot was also developed, relating the initial solids contents, digested sludge solids content, and organic solids fraction in the sludge at different degrees of degradation. VARIATION OF SLUDGE VOLUME INDEX WITH ACTIVATED SLUDGE CHARACTERISTICS,
Georgia Inst. of Tech. Atlanta. School of Civil Engineering.
M. Sezgin.
Water Research, Vol 16, No 1, p 83-88, January, 1982. 4 Fig, 1 Tab, 15 Ref.

Descriptors: *Sludge volume index, *Microorgansims, *Settling velocity, Suspended solids, *Activated sludge, Flocculation, Wastewater treatment, *Wastewater facilities.

Activated sludge samples from two laboratory sources and 12 sewage plants were used to investigate the variation of sludge volume index (SVI) with the quantity of filamentous microorgansims and floc size at different suspended solids concentrations. For a suspended solids concentration range of 700-4800 mg per liter, the SVI increased sharply with filament length concentrations of over 10,000,000 microns per mg suspended solids. At filament length concentrations less than 10,000,000 microns per mg suspended solids, SVI was unaffected by filament length but increased with increasing mean floc size. A well-defined relationship between SVI and zone settling velocity (cm per min) was found at all suspended solids concentrations examined. Maximum attainable SVI varied from 1429 to 208 mg per liter over the suspended solids concentration range, 700-4800 mg per liter. The zone settling velocities corresponding to the maximum attainable SVI were 2 to 0 cm per sec. This relationship was independent of the source and type of sludge, domestic or industrial. MULTIPERIOD DESIGN OF REGIONAL WASTEWATER SYSTEMS: GENERATING AND EVALUATING ALTERNATIVE PLANTS,
Louisville Univ., KY. Dept. of Chemical and Environmental Engineering.
M. Nakamura, E. D. Brill, Jr., and J. C. Liebman.
Water Resources Research, Vol 17, No 5, p 1339-1348, October, 1981. 8 Fig, 3 Tab, 11 Ref. OWRT A-082-ILL.

Descriptors: *Wastewater treatment, Planning, *Design criteria, Decision making, *Model studies, flow, Network design, *Wastewater facilities.

An extension was prepared of previous works dealing with the generation of single-period alternative solutions and the comparison of alternative regional plans using an impunted value analysis method. The primary purpose of the method is generation of multiperiod locations and facility expansion timings. The method is based on several simplifying assumptions. The solution procedure involves a branch and bound algorithm specifically developed for integrating a set of solutions obtained using the initial design flow with a set of solutions obtained using the terminal design flow. A method for comparing the generated multiperiod alternatives is also presented. The usefulness of the method is demonstrated with an example of a hypothetical regional wastewater system. A Fortran program was written to implement the method. Based on the simplifying assumptions, construction and operating and maintenance costs were reduced to functions of the initial and terminal design year flows, creating two decomposed problems. The two decomposed problems can be tied together using coupling constraints, and a coupled branch and bound process can be sued to obtain solutions. The method can generate many alternative plans besides the approximate least cost solution, and the imputed value incidence matrix can be provided. This approach represents a significant departure from conventional multiperiod public facility location analysis, and may be very useful for analyzing other water resources problems that include concave cost functions. WATER RECYCLING/REUSE IN THE FOOD PROCESSING INDUSTRY,
Montgomery (James), Inc., Walnut Creek, CA.
L. L. Russell, C. Creson, and K. Conarroe.
Industrial Wastes, Vol 27, No 5, p 25-28, September/October, 1981. 3 Fig, 1 Tab. OWRT C-9416.

Descriptors: *Water reuse, *Food processing industry, *Industrial water, Water conservation, Dairy industry, Meat processing industry, Poultry, Sugar refining, Wastewater reclamation, *Wastewater renovation, Wastewater treatment.

An evaluation of 10,000 U.S. food processing plants revealed the potential for water reuse/recycling in this industry. Reuse is defined as treated wastewater recycled within the facility; recycle is defined as multiple use of wastewater within the facility. Time and economic constraints limit a practical implementation to water conservation and recycling for the present. By the year 2000 increased costs and decreased water supplies may necessitate water reuse in some segments of the industry. Health and safety must be carefully considered in water recycling. Fruit and vegetable processing with terminal heat processing are intrinsically safer than meat and poultry packing, where the product is served to the consumer without heat treatment. Small plants will find it less practical to recycle water than large facilities. Water reuse presents further concerns: trihalomethanes production, concentration of pesticides, and pathogenic organisms. Major water-using food industries are sugar refining, canning and preserving fruits and vegetables, grain milling, meat packing, poultry dressing, dairy product manufacture, and beverages. Water reuse facilities at the Snokist Growers fruit processing plant in Yakima, Washington, and the Sterling Poultry Processing Corp., Maryland, are described. (Cassar-FRC)

THE EFFECTS OF PH AND SUSPENDED SOLIDS IN THE REMOVAL OF ORGANICS FROM WATER AND WASTEWATERS BY THE ACTIVATED CARBON ADSORPTION PROCESS,
Birmingham Univ. (England). Dept. of Civil Engineering.
R. J. Martin, and K. O. Iwugo.
Water Research, Vol 16, No 1, p 73-82, January, 1982. 13 Fig, 4 Tab, 32 Ref.

Descriptors: *Activated carbon, *Organic compounds, *Hydrogen ion concentration, *Suspended solids, *Wastewater treatment, Adsorption, Organic matter, Kaolin, Chlorophenol, Cresol, Bromocresol green, Inorganic compounds, Biological treatment, Effluents, Municipal wastewater.

The effects of pH and inorganic and organic suspended solids concentrations on activated carbon adsorption of organic compounds in municipal wastewater and effluents were studied in the laboratory using actual effluents and model solutions. The adsorption capacity and adsorption rate of carbon for o-chlorophenol and o-cresol (molecular weghts, 100-130) and bromocresol green (molecular weight, 700) were not affected by the presence of inorganic suspended solids up to 200 mg per liter kaolin. At the 500 mg per liter level adsorption of only the largest molecule was slightly depressed. The organic suspended solids (mixed liquor volatile suspended solids) at 0-200 mg per liter slightly decreased adsorption rates for the three compounds. At the 200-500 mg per liter concentration of organic suspended solids, adsorption rates for the three molecules were significantly reduced. Adsorption capacity was reduced for the two smaller molecules but not for bromocresol green. In both model solutions and sewage effluents adsorption was strongest in the acidic and basic pH regions (3-5 and 10-11), which favored the highest proportion of undissociated molecules. Although pH adjustment of municipal effluents to aid activated carbon adsorption is not justified, it may have an application in industrial wastewater treatment. (Cassar-FRC)

EVALUATION OF INSTRUMENTS FOR CONTINUOUS ACTIVATED SLUDGE MONITORING,
Environmental Protection Service, Burlington (Ontario). Wastewater Technology Centre.
J. P. Stephenson, E. G. Luxon, B. A. Monaghan, and R. G. Gillespie.
Water Science and Technology, Vol 13, No 11/12, p 721-728, 1981. 10 Fig, 4 Tab, 8 Ref.

Descriptors: *Measuring instruments, *Wastewater treatment, *Monitoring, Acidity, Dissolved oxygen, Suspended solids, Temperature, Flow rates, Organic carbon, *Activated sludge process.

The performance of selected commercial monitoring instruments including those for the measurement of dissolved oxygen, pH, suspended solids, temperature, flow and organic carbon has been evaluated. The pilot plant facilities used consist of two identical parallel activated sludge units with a common primary clarifier, and secondary clarifier surface areas. Degritted raw sewage is fed to the primary clarifier at a constant flow rate with uncontrolled variations in constituent concentrations. Primary effluent and return activated sludge are fed to each biological reactor with a maximum flow of 21.6 cubic meters/day. Diffused air is introduced through perforated PVC piping. Three identical dissolved oxygen instruments were monitored and compared to an air-calibrated reference YSI model 54 oxygen meter. Each instrument performed adequately for 141, 125, and 114 days before attention was needed. Two on-line mixed liquor suspended solids instruments and two RASS instruments were assessed by comparison to reference gravimetric analysis. One on-line self cleaning ISS analyzer and two flow-through ESS analyzers were evaluated by comparison to gravimetric results. The study concluded that suitable instruments exist for continuously monitoring the activated sludge process. The accuracies and instrument standard deviations measured indicate that instruments are sufficiently reliable for continuous monitoring and control functions associated with their use. Adequate maintenance and calibration are required if results are to be acceptable. (Baker-FRC)

DYNAMIC STEP FEED CONTROL FOR ORGANIC CARBON REMOVAL IN A SUSPENDED GROWTH SYSTEM,
Environmental Protection Service, Burlington (Ontario). Wastewater Technology Centre.
L. J. Yust, J. P. Stephenson, and K. L. Murphy.
Water Science and Technology, Vol 13, No 11/12, p 729-736, 1981. 7 Fig, 1 Tab, 13 Ref.

Descriptors: *Organic carbon, *Wastewater treatment, Wastewater facilities, Activated sludge process, Oxygen uptake, Process control, Effluent, Effluent variability reduction.

The objective of the present study was to reduce effluent variability from wastewater treatment operations. The study investigated the usefulness of SCOUR control (Specific Oxygen Utilization Rate), which is a dynamic indicator of sludge activity, the nature of pollutants, and the substrate reactor concentration. SCOUR is dependent on both the biological oxygen uptake rate and the concentration of activated sludge in the reactor. SCOUR control was achieved by using the step feed process when compared to a single tank completely-mixed process. Filterable organic carbon effluent data suggest that a reduced effluent variability can be obtained from a SCOUR control strategy during high loading periods. At low loading where SCOUR control was inadequate no improvement of SCOUR or effluent total organic

carbon variability was obtained in comparison with the system consisting of a single compartment completely mixed reactor with recycle. A further modification to the SCOUR controller constraints is required to obtain a unique optimal influent flow distribution if the SCOUR value of a three or more compartment system is to be controlled. The problem of increased effluent suspended solids concentrations must be addressed before SCOUR control can be fully evaluated. The maximum computing time for any one optimization did not exceed 10 minutes, making the iterative control presented acceptable for hydraulic time constants characteristic of the step feed activated sludge process. (Baker-FRC)

CONTROL AND AUTOMATION IN WASTEWATER TREATMENT - ADVANCES, UNSOLVED PROBLEMS AND CHALLENGES,
G. Olsson.
Water Science and Technology, Vol 13, No 11/12, p 826-831, 1981. 15 Ref.

Descriptors: *Wastewater treatment, *Automation, Computers, Reviews, *Activated sludge process, Process control, *Costs, *Operating costs.

A workshop was conducted on improving operation and reducing operating costs at wastewater treatment plants through obtaining a better understanding of the dynamics of the plant and the application of instrumentation and control. The activated sludge process is used as a model for the study, as it forms the heart of most wastewater treatment plants and usually reguires the highest expenditure of energy. A common objective for plant operation is to minimize the variability of the effluent quality. Effluent quality measurements are often crude. More study is also needed in the area of the linkage between sludge retention time and energy demand, settleability, clarifying properties and activity. The sludge blanket level is cricial for the settler and clarifier operation, but varies widely in practice. Many plants are operated so as to keep the mixed liquor suspended solids concentration constant, but there is seldom any apparent reason for doing so. Dissolved oxygen control has been recognized as a rewarding and meaningful control means, from both an economical and biological viewpoint. The availability of good sensors for wastewater treatment is not satisfactory, sometimes due to a lack of knowledge or proper attitude on the part of the user rather than the manufacturer. Extensive research has been performed during the last decade to develop dynamic models for wastewater treatment systems. (Baker-FRC)

AUTOMATIC OPERATION OF A FREEZE-THAWING AND DEWATERING PLANT FOR SEWAGE SLUDGES,
Mitsubishi Electric Corp., Hyogo (Japan).
T. Honda, S. Hiro, and K. Yamanishi.
Water Science and Technology, Vol 13, No 11/12, p 599-604, 1981. 5 Fig, 3 Ref.

Descriptors: *Automation, *Sludge drying, *Sludge thickening, *Freeze drying, Control systems, Process control, Sludge conditioning, Sludge solids, *Wastewater treatment, Hydrogen ion concentration, Pilot plants, Cost savings.

An automatic control system for a freeze-thawing method of sludge dewatering is described. In the freeze-thawing method, agglomeration of solid sludge occurs during freezing, and the specific filtration resistance is decreased from 10,000 m/kg to 10 to the 12th power m/kg. This allows reductions in sludge moisture content of up to 65 wt% with simple dehydrators, resulting in great decreases in the amount of sludge. Since no coagulant is required during the process, additional water pollution problems are avoided. A density sensor is installed in the thickener to signal when the slurry should be drawn out by a pump to a storage tank. pH monitors are used during pH conditioning, and freez-thawing is controlled by brine temperature and a timer. A pilot plant has used the process with little trouble for over two years. The method is economically competitive with other dewatering techniques and reduces the mass of the dewatered cake to 1/2.5 of that of conventional methods. (Geiger-FRC)

APPLICATION EXAMPLES OF AND OPERATING EXPERIENCES WITH THE USE OF PROCESS COMPUTERS IN SEWAGE TREATMENT PLANTS,
Siemens A.G., Karlsruhe (Germany, F.R.).
E. F. Michel.
Water Science and Technology, Vol 13, No 10, p 483-488, 1981. 4 Fig, 5 Ref.

Descriptors: *Process control, *Computers, *Wastewater treatment, *Automation, Monitoring, Data processing, Wastewater facilities, Control systems, Operating costs, Electronic equipment, Maintenance costs, Netherlands, Sweden, Germany, Comparison studies.

The operating expeeriences of three sewage treatment plants, the Deventer facility (The Netherlands), the Malmo-Sjolunda plant (Sweden), and the Regenburg plant (Germany) are reviewed. The Deventer plant, which serves a population of roughly 120,000, is equipped with a SAMSY automated process control system. This system has been operating favorably since 1967 and has saved on energy costs, material, and personnel. The Swedish plant serves approximately 530,000 and features two central control stations. The entire process at the Malmo-Sjolunda plant is controlled and monitored by the SIMAT C/SAMSY automation system with the SIMATIC electronic control system as a backup for manual and remote controls. The Regensberg facility was designed to handle a population of 300,000 but plans to handle 400,000. This plant also uses the SIMAT C/SAMSY system along with free programmable electronic controls. These automated systems have improved process control, decreased power costs and reduced maintenance in the aforementioned plants. A new automation system concentrating on decentralized intelligence, the TELEPERM M, is also described. (Geiger-FRC)

EXPERIENCE WITH COMPUTER CONTROL OF WASTEWATER TREATMENT PROCESSES AT LOS ANGELES AND OTHER COMMUNITIES,
Los Angeles Bureau of Sanitation, CA.
W. F. Garber, and J. J. Anderson.
Water Science and Technology, Vol 13, No 11/12, p 759-770, 1981. 3 Fig, 1 Tab, 2 Ref.

Descriptors: *Wastewater treatment, *Computers, *Automation, Design criteria, Reviews, *Los Angeles, California, Municipal wastewater, Process control, Case studies.

Case study reviews were made of computer controlled wastewater treatment centers at the Hyperion treatment plant at Los Angeles, the Terminal Island treatment plant in Los Angeles, and the Glendale Water Reclamation Plant in Los Angeles, as well as treatment plants in Cleveland, Ohio; Bridgeport, Connecticut; Philadelphia, Pennsylvania; and Moorhead, Minnesota. The studies suggest that it is very difficult to provide isolated environmentally controlled spaces for computers in a wastewater treatment plant. Voltage or current variations lasting for microseconds could drastically affect the computer control systems when such systems were not isolated electrically from the power system supply lines. An analog control loop or other means of control should be provided for selected critical steps or processes, and these should be interfaced with the central processing computer. Computer control systems should not be designed as hybrid systems to handle process control and data processing. Conditions other than maximum should be considered during the design stage. The complexity of the computer control system and the frequency of measurement needs to be carefully studied prior to design. A prime manufacturer/installer should be selected who has the ability and desire to make an installed system work as designed. Cities and operating authorities must provide in advance the necessary trained and dedicated personnel. A number of large central process control computers are not meeting the reliability requirements needed for their acceptance as a useful tool for wastewater control. (Baker-FRC)

AUTOMATIC CONTROL OF SOLIDS RETENTION TIME AND DISSOLVED OXYGEN IN THE ACTIVATED SLUDGE PROCESS,
Environmental Protection Services, Burlington (Ontario). Wastewater Technology Centre.
J. P. Stephenson, B. A. Monaghan, and P. J. Laughton.
Water Science and Technology, Vol 13, No 11/12, p 751-758, 1981. 6 Fig, 1 Tab, 10 Ref.

Descriptors: *Wastewater treatment, *Automation, Computers, *Activated sludge process, *Dissolved oxygen, Monitoring, Solids, retention time.

This paper summarizes the dissolved oxygen (DO), solids retention time (SRT), and oxygen uptake rate (OUR) control approaches investigated at pilot scale. The pilot plant consisted of two identical parallel activated sludge units. The results indicate that a computer controlled facility can provide control of the instantaneous SRT equivalent to a well operated manually controlled plant. Energy savings and improved process operating conditions are achieveable through automatic dissolved oxygen control in activated sludge systems. The use of on-line process analyzers for flow and suspended solids, interfaced to a process computer, can provide effective solids inventory control in activated sludge systems. Automatic SRT control can provide solids inventory control equivalent to that achieved in a well controlled manually operated plant. No significant difference can be expected in the effluent quality based on effluent suspended solids. The use of OUR for control of plant solids inventory can be automated readily and merits further development and evaluation. (Baker-FRC)

WASTE WATER TREATMENT PLANT RELIABILITY - ENGINEERING DESIGN FOR FAILURE AND ECONOMIC GAIN,
UKAEA Systems Reliability Service, Warrington (England).
K. C. Hignett, and B. Sayers.
Water Science and Technology, Vol 13, No 11/12, p 743-750, 1981. 5 Fig.

Descriptors: *Mathematical models, *Wastewater treatment, Water treatment facilities, *Wastewater facilities, *Design criteria, Economic aspects, Engineering, Systems engineering, Case studies.

Quantified assessments of systems' availability may be derived on the basis of fault tree logic and mathematical modelling. The techniques described require a knowledge of representative failure data and downtimes. A data collection and availability modeling procedure were developed. A case study on sixteen wastewater plants was performed over a three year period, beginning in mid 1978. The study related to primary sedimentation systems, but the techniques are applicable to any system where basic failure data can be obtained. The analyses enabled weak areas in the systems to be identified and recommendations made for improving reliability. The results often confirmed the intuitive feelings of plant managers and made it possible to quantify the effects of different proposed improvements. The increased application of reliability technology can provide an important contribution to the realization of more efficient and lower cost waste water processing systems. (Baker-FRC)

LIBRARY U. OF I. - URBANA-CHAMPAIGN

Descriptors: *Activated sludge process, *Control systems, *Model studies, Mathematical studies, Wastewater treatment, Water quality, Monitoring.

This paper assesses the feasibility of some estimation and control schemes applied to the time varying operation of the Activated Sludge Treatment Process (ASTP). Real-time control of ASTP is becoming a significant issue in the context of water quality management. Preliminary results concerning the estimation of process variables are presented, and some new control concepts which imply the notions of optimality and energy conservation are introduced. Estimation and control algorithms developed are based on a reduced order model, thus making them easily implementable on microprocessors. Numerical simulation results are presented and discussed to assess the relative merits of the various algorithms. While far from exhaustive, this partitioned approach as demonstrated has shown the viability of Extended Kalman Filtering (EKF) state/parameter estimation and of optimal feedback control. Simulations have shown that improved performance and energy conservation can be achieved by using biochemical oxygen demand as a direct control variable. A foreseeable extension of the EKF properties concerns the inclusion in the performance index of some measure of upstream quality. In this way, the treatment cost can be made dependent of the present condition of the receiving water body. This, in addition to providing very sensible set points for diurnal operation, may help reduce treatment costs in many cases of medium or high flow conditions. (Baker-FRC)

PULSED-BED TECHNIQUE CAN CUT TREATMENT STAGES,
J. Irwin.
World Water, Vol 4, No 12, p 42-43, December, 1981. 1 Fig, 5 Tab.

Descriptors: *Percolating filters, *Backwash, Effluent, *Wastewater treatment, *Filtration, Sand filters, Filters, Separation techniques, Costs, Filter media, Clarification, Sludge treatment.

Pulsed-bed filtration is being used increasingly for primary effluent filtration (PEF) to reduce secondary treatment costs in municipal sewage plants as part of plant upgradings or expansions. Pulsed-bed units have a much shallower filter cell than conventional filters and can operate at heads of 0.6-1.5 m. They can accommodate high loading rates and cost less to backwash due to a special air diffuser device over the media surface. A pulse mix system helps fold the majority of particles into the media, while a screen media-retaining system permits filter media to be placed directly on top of the underdrain system for improved backwashing. A chemical detergent is used during backwashing, and a backwash control system recycles backwash water to a separate clarifier. The Hydro Clear Corporation has experimented with placing a pulsed-bed filter after the primary clarifier at several pilot plants. These efforts showed that primary clarification, PEF, and trickling filtered produced secondary quality effluent without final clarifiers at great cost reductions. Sludge treatment was also easier with PEF. Hydro Clear is developing a fine-sand pulsed-bed filtration technique for algae removal which may also be useful in potable water development and wastewater reuse. (Geiger-FRC)

DETOXIFICATION OF WASTE WATER CONTAINING CYANIDES FROM THE WET-SCRUBBING SYSTEMS OF STEEL MILLS (ENTGIFTUNG CYANIDHALTIGEN GICHTGASWASCHWASSER VON HOCHOFEN),
Hanover Univ. (Germany, F.R.). Inst. fuer Siedlungswasserwirtschaft.
B. Fischer, H. Ruffer, W. Duppers, G. Nagels, and H. Knorre.
Zeitschrift fur Wasser und Abwasser Forschung, Vol 14, No 5/6, p 210-217, 1981. 5 Fig, 1 Tab, 6 Ref.

Descriptors: *Wastewater treatment, *Industrial wastewater, *Cyanide, *Steel industry, Effluents, Wastewater oxidation, Hydrogen peroxide, Formaldehyde, Catalysts, Weser River, Standards, *Germany.

Blast-furnace stack gas in steel mills is wet-scrubbed prior to utilization of its heat content. At the Bremen plant of the Klockner-Werke AG, process water is withdrawn from the Weser River; prior to return it must be treated to meet effluent standards, including a cyanide ceiling of 0.1 mg/liter. Various treatments for oxidative cyanide detoxification in scrubber water were considered: hypochlorite, ozone, catalytic oxidation with active carbon, peroxydisulfates, potassium permanganate, hydrogen peroxide, hydrogen peroxide/formaldehyde, and peroxymonosulfuric acid. Following laboratory trials, pilot tests were set up using the last four methods. The hydrogen peroxide-formaldehyde process was selected for full-scale trails. The initial settling basin was selected as the site for chemical introduction, since the turbulence of the inflowing stack gases provided adequate mixing. Sodium hydroxide was added to raise the pH of this water to 9-10. Chemical addition was metered via a sample stream. The goal of purifying the average flow of 1400 cu m per hour of wastewater at a maximum cyanide ion content of 50 mg/liter to register less than 0.1 mg/liter was attained during 93.5% of the measurement intervals in 6 months of operation. The standard for effluent from the settling basin, 1 mg/liter, was exceeded in 2.5% of the intervals, mostly for brief periods, due to operational problems. Chemical costs were about 2700 German Marks per day; the relatively high labor costs were primarily attributable to analytical requirements. The plant operated reliably even under the intensified demands caused by blast furnace shutdown. (Carroll-FRC)

DEMONSTRATION OF ZINC CYANIDE RECOVERY USING REVERSE OSMOSIS AND EVAPORATION,
Abcor, Inc., Wilmington, MA.
K. J. McNulty, and J. W. Kubarewicz.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-231243, Price codes: A03 in paper copy, A01 in microfiche. Environmental Protection Agency EPA-600/S2-81-132, September, 1981. 6 p, 3 Fig, 6 Ref. R805300.

Descriptors: *Metal-finishing wastes, *Reverse osmosis, *Evaporation, *Wastewater treatment, *Water reuse, Industrial wastewater, Zinc, Cyanide, Cost analysis, *Zinc cyanide recovery.

A field test was conducted to demonstrate closed-loop recovery of zinc cyanide rinse-water at a job shop plating facility. Since the zinc cyanide bath operates at room temperature with very little evaporation from the bath, reverse osmosis (RO) treatment of the rinsewater must be supplemented by evaporation in order to achieve the volume reduction necessary for return of a concentrate to the plating bath. The permeate from the RO unit was recycled to the first rinse after plating, while the distillate from the evaporator was recycled to the second rinse after plating. Spiral-wound PA-300 membrane modules were used in the RO unit. A gradual loss in membrane performance is attributable to fouling of the membrane by particulates in the rinsewater. Such fouling can be reduced by better prefiltration and reversed by periodic cleaning. The economics of the combined RO evaporation system were assessed for a system designed to provide rinsing equivalent to the present two-stage counter-current rinse at the demonstration site. The total operating cost was somewhat less for the combined RO evaporation system than for evaporation alone. However, credits for rinsewater recovery were insufficient to completely off-set the total operating cost of the recovery system. (Moore-SRC)

EVALUATION OF A TREATMENT LAGOON FOR COMBINED SEWER OVERFLOW,
Environmental Design and Planning, Inc., Boston, MA.
D. J. Connick, W. C. Pisano, and GL. Aronson.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-105214, Price codes: A06 in paper copy, A01 in microfiche. Environmental Protection Agency, EPA-600/S2-81-196, December, 1981. 7 p, 6 Tab, 1 Ref. 11023FAV.

Descriptors: *Wastewater lagoons, *Combined sewer overflows, Disinfection, Stabilization lagoons, *Wastewater treatment, Industrial wastewater, Chlorination, Chlorine dioxide, Aerators, Oxygenation, *East Chicago, *Indiana.

The East Chicago Sanitary District operates a wastewater treatment plant that handles about 19 mgd of dry weather municipal wastewater from the city of East Chicago, Indiana. The sewerage system has combined sewers with overflows containing direct industrial discharges and runoff from industrial areas. The world's largest facultative lagoon was constructed tere to polish the secondary effluent from the wastewater treatment plant and to provide preliminary treatment with disinfection to the combined sewer overflows. Volume of the lagoon is estimated to be 142.2 million gal. Results of a two-year evaluation of the East Chicago lagoon indicate that relatively good treatment can be provided by a deep stabilization pond. During dry weather flow periods, the lagoon provided removal capabilities of 30 to 70% for the secondary effluent, depending on the parameter. The reoxygenation function of the aerators was found to be necessary. Under most circumstances, four aerators were adequate, but at times of high organic loading, the use of all eight appeared to be more advantageous. Disinfection results indicated that chlorination should be used until more reliable chlorine dioxide equipment is provided. The chlorine dioxide system should be reconstructed to provide extensive mixing upon initial disinfection, and it should provide a 15 to 30 second delay time between doses. (Moore-SRC)

PARALLEL EVALUATION OF AIR- AND OXYGEN-ACTIVATED SLUDGE,
Los Angeles County Sanitation Districts, Whittier, CA.
S. Austin, and D. Wuerdeman.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-246712, Price codes: A04 in paper copy, A01 in microfiche. Environmental Protection Agency, EPA-600/S2-81-155, September, 1981. 6 p, 5 Tab. 14-12-150.

Descriptors: *Activated sludge, *Wastewater treatment, *Secondary wastewater treatment, *Pilot plants, Aeration, Nitrification, Denitrification, Clarification, Trace metals, Organic compounds, Solids, Comparison studies, Carson, California.

To provide data on the relative merits of air and of oxygen in the activated sludge process, two 1,900 cu m/day activated sludge pilot plants were operated side-by-side at the Joint Water Pollution Control Plant, Carson, California. One incorporated the UNOX high-purity oxygen process, and one used an air-sparged mechanical aerator. Although both pilot plants met the applicable discharge limitations for everything but three trace metals, the oxygen system provided a more stable operation. The two systems obtained good removals of soluble organics, and factors affecting solids separation in the final clarifier are most significant in terms of their effects on effluent quality. The most notable detrimental factors encountered in the study were excessive input of aerator power, which sheared the flocs in both systems and nitrification-denitrification, which caused the settled sludge from the air system to resuspend. The oxygen system did not nitrify. Claims have been made that oxygen-activated sludge processes produce less sludge than air-activated sludge processes. In this study, the total plant solids were compared and the difference was found to be insignificant at the 90% confidence level. The results of power consumption estimates indicate that the oxygen systems use substantially less energy. (Moore-SRC)
W82-04624

TREATMENT EFFECTIVENESS: OIL TANKER BALLAST WATER FACILITY,

Rockwell International, Newbury Park, CA.
I. Lysyj.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-101361, Price codes: A09 in paper copy, A01 in microfiche. Environmental Protection Agency, EPA-600/S2-81-192, October, 1981. 6 p, 3 Fig, 2 Tab. 68-03-2648.

Descriptors: *Ballast, *Oily water, *Oil tankers, *Wastewater treatment, Fjords, Trap zone, Stratification, Alaska, Hydrocarbons, Effluent, Organic compounds, Organic loading, Water pollution sources, Valdez, Alaska.

The large, modern ballast water treatment plant at the Valdez, Alaska, marine terminal was studied using specially developed chemical analytical methods to determine the effectiveness of each unit process and to characterize compositional changes in the process stream. The studies disclosed that the state-of-the-art processes are generally effective in reducing the free oil content of the oily wastewater discharged from arriving tankers. A reduction of more than 99.8% in the organic load of the process stream is realized with ballast water treatment by gravity separation, dissolved air flotation, and retention in polishing ponds. Less effectively removed, however, are the water soluble fractions of the oily wastewater, which often include five priority pollutants: benzene, toluene, ethylbenzene, phenol, and naphthalene. Such priority pollutants make up more than 50% of the total organic load in the effluent from the ballast treatment plant, and they are discharged in significant quantities into the receiving waters of Port Valdez. The plant discharges approximately half a metric ton of organic carbon each day. Included in this daily dischargew are 102 L of benzene, 91 L of toluene, 45 L of ethylbenzene/xylenes, 27 kg of phenol, and 2.8 kg of naphthalene. Because benzene, toluene, and ethylbenzene/xylenes constitute a significant fraction of the total organic discharge, their distribution in the receiving waters was studied. During the summer months, when the waters of the fjord are stratified, the effluent does not mix uniformly with the receiving waters, but forms a submerged field of diluted effluent. The aromatic hydrocarbons are contained at a depth of 50 to 70 m in a thin trap zone that spreads horizontally as far as 2 to 3 km from the plant outfall. The top of the trap zone moves progressively farther below the surface as the summer heating season progresses, from 50 m in June to 65 m in September. No aromatic hydrocarbons were found in the fjord outside the confines of the trap zone.

THE DEVELOPMENT OF DESIGN EQUATIONS FOR FACULTATIVE WASTE STABILIZATION PONDS IN SEMIARID AREAS,
J. P. Arthur.
Proceedings of the Institution of Civil Engineers, Part 2: Research and Theory, Vol 71, No 1, p 197-213, March, 1981. 13 Fig, 10 Tab, 14 Ref.

Descriptors: *Waste treatment, *Stabilization ponds, *Wastewater treatment, Temperature, Organic loading, Detention time, Bacteria, Sewage bacteria, Biological oxygen demand, *Nigeria, Semiarid lands, Ponds, Performance evaluation, Design criteria.

A comprehensive pilot scale study of waste stabilization ponds was conducted in semiarid northern Nigeria for a year. Two small ponds and 44-gal oil drums were arranged in various parallel and series combinations to investigate the effects of climatic factors and changes in organic loadings and detention times. The experimental systems provided excellent BOD and fecal bacteria removal. Anaerobic conditions occasionally developed as a result of overloading, but facultative operation became reestablished when favorable conditions returned. Temperature had a more significant effect on BOD and fecal bacteria removal than solar insolation. Equations were developed to aid in design of waste stabilization pond systems. Series ponds were more effective than single units. Other factors which promoted treatment efficiency were complete mixing, increased detention time, and optimum organic loading. (Cassar-FRC)

PILOT STUDIES OF THE NITRIFICATION PROCESS IN FIXED FILM REACTORS (PILOTVERSUCHE ZUR NITRIFIKATION IN FESTBETTREAKTOREN),
Hamburg Univ. (Germany, F.R.).
I. Sekoulov, and D. Heinrich.
Wasserwirtschaft, Vol 71, No 11, p 331-333, 1981. 4 Fig, 2 Tab, 3 Ref. English summary.

Descriptors: *Aerobic digestion, *Wastewater treatment, *Nitrification, Pilot plants, Fixed film reactors, *Germany.

The ability of nitrifying bacteria to grow attached to solid surfaces can be optimally utilized in fixed film reactors in order to concentrate them in a system. After the growth phase of the nitrifiers is complete, the hydraulic loading (residence time) is of practical importance for the nitrification behavior of the fixed bed reactor. Nitrifiers show ability to adapt to low oxygen concentrations and pH values, especially when they have been grown under these conditions. The nitrifiers produce very thin biological films which in themselves do not cause clogging of the reactors. However, when used in wastewater treatment the fixed bed reactors encounter suspended solids. In such cases it is necessary to provide the possibility for back-washing. The filler materials must permit uniform circulation. Expanded clay beads have proven to be acceptable filler materials. The proper size of a fixed-bed reactor can be selected with the aid of the Michaelis-Menten equation. Pilot-scale studies were conducted with two conventional fixed bed reactors, connected in parallel, and a completely immersed, rotating fixed bed reactor. In the case of non-limiting ammonium concentrations and short residence times, e.g., 0.5 hr, a maximal nitrification speed relative to the surface area of the filler material of 58.7 mg ammonium nitrogen per sq m per hr was achieved. If the nitrification rate is calculated relative to the reactor volume, the result is about 10 times higher than previously available values for activated sludge plants. (Carroll-FRC)

COMPARATIVE DISINFECTION OF POLIOVIRUS BY BROMINE CHLORIDE AND CHLORINE IN A MODEL CONTACT CHAMBER,
Hawaii Univ., Honolulu. Dept. of Tropical Medicine.
B. H. Keswick, R. S. Fujioka, N. C. Burbank, and P. C. Loh.
Water Research, Vol 16, No 1, p 89-94, January, 1982. 1 Fig, 3 Tab, 15 Ref.

Descriptors: *Disinfection, *Viruses, *Halogens, *Wastewater treatment, *Bromine chloride, *Chlorine, Chlorination, Poliovirus, Ammonium.

Bromine chloride proved superior to chlorine in inactivating poliovirus in 0.00009 M ammonium chloride solution and water containing 10% sewage effluent. In clear tap water both BrCl and Cl at doses of 0.5 and 2.0 mg per liter were effective disinfectants for poliovirus. The apparatus used for the studies was a 4 gal per min model contact chamber built to simulate conditions in a wastewater treatment plant. Concentrations of poliovirus in the initial mixture were 100,000 PFU per ml. The 2.0 mg per liter dose of BrCl was effective under all conditions. The 2.0 mg per liter dose of Cl failed to inactivate sufficient poliovirus when sewage effluent was present. (Cassar-FRC)

TEMPERATURE DEPENDENCY OF BIOLOGICAL DENITRIFICATION WITH ORGANIC MATERIALS ADDITION,
Polish Academy of Sciences, Zabrze. Inst. of Environmental Engineering.
Z. Lewandowski.
Water Research, Vol 16, No 1, p 19-22, January, 1982. 1 Fig, 2 Tab, 12 Ref.

Descriptors: *Temperature, *Kinetics, *Denitrification, *Organic compounds, Biological treatment, *Wastewater treatment, Activated sludge process, Nitrogen removal, Methanol, Acetone, Acetic acid.

The rate of denitrification in a wastewater treatment process depends on temperature and on the compound used as the electron donor. Fresh activated sludge was incubated in laboratory plastic containers at eight temperatures from 2.5 to 35 C. Nitrate was added, followed by the organic compound, methanol, acetone, or acetic acid. Kinetic constants for the reactions are presented. Acetic acid was most effective in increasing the denitrification rate, acetone showed no improvement, and methanol was intermediate. The Arrhenius activation energy was similar in all cases, 10.9-12.3 kcal per mol. (Cassar-FRC)

TREATMENT OF NONCYANIDE ELECTROPLATING CADMIUM WASTEWATER BY REVERSE OSMOSIS,
Shanghai Inst. of Mechanical and Electrical Engineering (China).
F. Menwei, B. Tingyong, L. You, and Z. Aili.
Water Science and Technology, Vol 13, No 11-12, p 517-522, 1981. 3 Fig, 1 Tab.

Descriptors: *Cadmium, *Separation techniques, *Reverse osmosis, *Electroplating, *Wastewater treatment, Industrial wastes, Heavy metals, Membrane processes, Osmosis, Water pollution prevention, Chelating agents, Industrial wastewater.

Since cadmium (Cd) is hazardous to the environment and human health, the removal of Cd from the wastewaters of industries using Cd electroplating is an area of constant consideration. Reverse osmosis, a membrane separation technology, has been applied to noncyanide electroplating Cd rinse water. Closed-loop rinse systems using cellulose acetate membranes were tried in laboratory and pilot plant tests. The reverse osmosis units were of an out-press tubular structure and gave an average flux of 17 liters/sq m-h. At an operating pressure of 30 kilograms/sq cm Cd rejections of 95-98% were obtained. The reverse osmosis installation and its attachments require only 10 sq m of space and can restore 99% of the amount of Cd previously discharged. The present system when aided by some simple controllers was found to be suited for small-scale wastewater treatment operations. (Geiger-FRC)

ON LINE CONTROL OF PHARMACEUTICAL INFLUENT LOADS TO A BIOLOGICAL WASTEWATER TREATMENT PLANT,
OTV, Coubevoie (France).
A. Minier, H. Moreaud, G. Castelnau, and M. Mevolhon.
Water Science and Technology, Vol 13, No 11-12, p 523-529, 1981. 5 Fig.

Descriptors: *Biological wastewater treatment, *Flow regulators, *Activated sludge, *Respiration, *Wastewater treatment, Process control, Biodegradability, Fluctuations, Industrial wastes, Biological treatment, Pollution load, Control systems, *Pharmaceutical wastes.

A special pollution flux-regulator for the biological treatment of effluents in cases where the composition and flow rate are subject to considerable variation is described. The system is an industrial application of the metabolization technique in which wastewater is batch injected into a reactor containing activated sludge. A rapid respirometric test shows the affinity between the influent and the sludge bacteria and from this the biological reaction parameters are deduced. These parameters are then used to calculate the maximum load and hydraulic properties of the facility. This system has been successfully operated since July of 1980 for the treatment of wastes from the SAPCHIM pharmaceutical factory at Sisteron, France. An on-line biodegradability analyzer helps to regulate the flow between the storage tank and the contact tank of a biological treatment line by a contact-stabilization process. (Geiger-FRC)

OPTIMIZATION OF AREAWIDE WASTEWATER MANAGEMENT,

LIBRARY U. OF I., URBANA-CHAMPAIGN

Landfills, Slope stability, Soil properties, Soil mechanics, *Minnesota, Water pollution control, *Solid waste disposal, Dikes, *Clay Boswell Generating Station.

The planning, construction, and operation of a solid waste disposal pond for the Clay Boswell Generating Station, Minnesota, are described. This fossil fuel-burning plant is expected to produce 12.3 million cu m of solid waste (fly ash, bottom ash, and SO2 scrubber sludge) over its 35-year life. Wet ponding was chosen over two alternatives, chemical stabilization for landfill disposal and disposal in open pit iron mines. Boring tests located a suitable pond site with a continuous subsurface clay layer. The soils were further studied in the laboratory. The final design for the pond was an embankment built of random soil with a clay lining constructed on the upstream embankment slope. The entire pond was clay lined and soil-bentonite slurry cut-off trenches were installed down to the natural clay layer. Seepage calculations predicted a total long-term steady state seepage rate of 450 gal per acre per day. The pond, constructed during 1978 and 1979, consists of three compartments divided by earth dikes. Ash is kept covered with 2 ft of water. Piezometers, settlement mounments, and visual inspections are used for monitoring pond performance, which had met design expectations. A seepage problem in one compartment was the result of a frozen dividing dike. A reverse filter drainage system was constructed in the problem area to relieve the excessive piezometric head. DENSITY LEVELS OF PATHOGENIC ORGANISMS IN MUNICIPAL WASTEWATER SLUDGE - A LITERATURE REVIEW,
Camp, Dresser, and McKee, Inc., Boston, MA.
D. C. Pederson.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-102286, Price codes: A13 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-170, October, 1981. 5 p, 2 Tab. 68-03-2803.

Descriptors: *Sludge drying, *Pathogens, *Disinfection, Parasites, *Viruses, *Bacteria, *Wastewater treatment, Literature review, Public health, Indicators, Lime, Anaerobic digestion, Composting, Aerobic digestion, Pathogenic fungi, Eggs, Sludge disposal.

Sludges originating from municipal wastewater treatment plants harbor a multitude of microorganisms, many of which present a potential health hazard. A literature review of available domestic and foreign data from 1940 to 1980 was undertaken concerning bacteria, viruses and parasites densities in raw municipal wastewater sludges, on the effectiveness of the 'Processes to Significantly Reduce Pathogens' (40 CFR Part 257), and on conventional sludge dewatering techniques to reduce levels of these organisms. Anaerobic digestion and lime stabilization consistently produce reductions of about 1 to 2 logs in densities of indicator and pathogenic bacteria, and in the case of anaerobic digestion, in densities of viruses as well. Conditions of mesophilic composting may inactivate common indicator and pathogenic bacteria and viruses, provided that specified temperatures are attained uniformly throughout the compost mass. The pathogenic fungus Aspergillus fumigatus thrives under conditions of mesophilic composting. Density reductions of bacteria by aerobic digestion are variable and of relatively small magnitudes. Sludge lagoons can achieve 1-log reductions in densities of bacteria and viable parasite ova, but storage of one month to more than three years may be required. Mechanical dewatering of sludge, with or without the use of chemical conditioners, has little reliable effect on densities of pathogens. (Moore-SRC)

DEEP WELL DISPOSAL OF SECONDARY EFFLUENT IN DADE COUNTY FLORIDA,
CH2M/Hill Inc., Gainesville, FL.
U. P. Singh, J. I. Garcia-Bengochea, and C. R. Sproul.
Water Resources Bulletin, Vol 16, No 6, p 812-817, October, 1980. 4 Fig, 3 Tab, 5 Ref.

Descriptors: *Wastewater disposal, *Deep wells, *Transmissivity, Groundwater movement, *Injection wells, Underground waste disposal, Environmental effects, Groundwater management, Geophysics, Wastewater management, Subsurface drainage, Aquifer management, Aquifers, *Florida, Saline water intrusion, Dade County.

Drilling and testing were carried out on a test injection well site for deep underground injection of wastewater effluent from the proposed 50 mgd South District Regional Wastewater Treatment Plant of the Miami-Dade Water and Sewer Authority. The total depth of the well is 3,200 ft. The Boulder Zone, a highly cavernous and transmissive aquifer with water much like seawater, begins at 2,790 ft in depth. This zone is separated from the Floridan aquifer above it by about 1,100 ft of confining limestone layers. Packer testing proved these limestone layers very effective in separating the Boulder Zone, the proposed injection area, from the aquifer above. The transmissivity of the Boulder Zone was estimated at 14 million gallons/day/ft from pump-out test data. An 8,000 gallon/minute injection test was performed to evaluate well performance under operating conditions. A detailed monitoring program consisting of subsurface wells in various strata will be provided to monitor injection rate, injection pressure and effluent quality. A possible remedial action for salt water migration into the Floridan aquifer would be the construction of relief wells in the lower part of the aquifer. It was concluded that underground injection of secondary wastes from the proposed treatment facility is a feasible and cost-effective plan, both hydraulically and environmentally. (Geiger-FRC)

U.S. GEOLOGICAL SURVEY RESEARCH IN RADIOACTIVE WASTE DISPOSAL--FISCAL YEAR 1979,
Geological Survey, Reston, VA. Water Resources Div.
R. Schneider, E. H. Roseboom, Jr., J. B. Robertson, and P. R. Stevens.
Available from Br. of Distr., USGS 604 South Pickett St. Alexandria, VA 22304. Geological Survey Circular 847, 1982. 74 p, 15 Fig, 79 Ref.

Descriptors: *Radioactive waste disposal, *Geological surveys, *Waste storage, *Water pollution sources, Environmental effects, Waste management, Geology, Hydrology, Geochemistry.

The report summarizes progress on geologic and hydrologic research related to the disposal of radioactive wastes. The research is described according to whether it is related most directly to: (1) high-level and transuranic wastes; (2) low-level wastes, or (3) uranium mill tailings. Included is research applicable to the identification and geohydrologic characterization of waste-disposal sites, investigations of specific sites where wastes have been stored, and studies of regions or environments where waste-disposal sites might be located. A significant part of the activity is concerned with techniques and methods for characterizing disposal sites and studies of geologic and hydrologic processes related to the transport and(or) retention of waste radionuclides. AUTOMATIC CONTROL OF THE SEWAGE SLUDGE PYROLYSIS PROCESS IN MULTIPLE HEARTH FURNACE,
NGK Insulators, Ltd, Nagoya (Japan).
T. Kasakura, T. Majima, and N. Izumi.
Water Science and Technology, Vol 13, No 11-12, p 605-610, 1981. 3 Fig, 1 Tab.

Descriptors: *Incineration, *Sludge disposal, *Cost analysis, *Solid waste disposal, Automation, Control systems, Waste disposal, Sludge, Monitoring, Process control, Solid wastes.

An automatic control system for a 60 T/day sewage sludge pyrolysis plant with multiple hearth furnace has been developed as an energy-saving alternative to conventional incineration. The new control system maintains the required furnace temperature through control of the partial combustion ratio of the furnace by adjusting the amount of air supplied to the furnace. It also features stable automatic gas analysis and monitoring under severe conditions. A feed forward method is used to control the furnace and combustion chamber pressure, and the steam line of the waste heat boiler is designed so that some steam may be recycled other uses. These features result in a fuel comsumption one third that of conventional incineration methods. (Geiger-FRC)

AUTOMATIC CONTROL OF SLUDGE CONDITIONING AND VACUUM FILTRATION,
EMA, Inc., St. Paul, MN.
D. I. Knudsen, and G. A. Mathes.
Water Science and Technology, Vol 13, No 11/12, p 611-617, 1981. 6 Fig, 1 Tab.

Descriptors: *Sludge conditioning, *Vacuum filtration, Costs, Automation, Computers, *Activated sludge process, Sludge, Filtration, *Sludge disposal, Incineration, Process control.

This paper reports progressive development of control strategies and the resultant benefits derived from the Seneca Treatment Plant in Eagen, Minnesota. The plant is a 24 mgd activated sludge plant with two paralles 12 mgd trains. Two identical sludge processing trains consist of flotation thickeners, sludge holding tanks, chemical conditioning with ferric chloride and calcium hydroxide, vacuum filters, multiple hearth incinerator, and ash disposal by one common pipeline to a remote ash pond. The developmental nature of the project required a flexible control system. A microcomputer-based remote terminal unit communicates with a minicomputer over a four-wire asynchronous 1200 baud link. The minicomputer with its operations console is located in a buliding remote from the sludge disposal building. Various types of sludge conditioning and vacuum filter automatic process control resulted in economic benefits. The highest savings are achieved with a multivariable model based control strategy. Instrumentation requirements are met with proven equipment that does no require excessive maintenance. Properly applied sludge conditioning control strategies reduced ferric and lime usage, stabilized performance, increased production capacity, improved incinerator performance and decreased fuel usage. Operator and laborer requirements can be reduced because the control system can maintain continuity of stable operation with various sludge and chemical qualities. (Baker-FRC)

DENSIFICATION OF PAPER MILL SLUDGE MATERIALS,
Michigan State Univ., East Lansing. Dept. of Civil Engineering.
O. B. Andersland, A. W. N. Al-Khafaji, and R. K. Loew.
Journal of the Geotechnical Engineering Division, Proceedings of the American Society of Civil Engineers, Vol 108, No HY1, p 1-15, January, 1982. 5 Fig, 1 Tab, 13 Ref.

Descriptors: *Dewatering, *Pulp and paper industry, *Compressibility, Sludge thickening, *Sludge disposal, Organic matter, Decomposition, Landfills, Void ratio, Waste disposal.

Densification of model paper mill sludges made from kaolinite and pulp fibers was studied to predict settlement of decomposing sludges. Densification involves removal of additional water from dewatered sludge, usually by placing surcharge loads in a landfill. Ignition tests were used to determine the organic content, and compression tests to follow the course of decomposition. The relationship between void ratio and organic fraction for a constant stress level was shown to be linear for the model sludges. A method was developed to calculate the void ratios as a function of pressure and organic content. These values agreed well with field data. Predictions of settlement of

decomposing sludges were formulated from the initial and final void ratios and the degree of decomposition. (Cassar-FRC)

APPLICATION OF THE WASTEWATER EFFLUENT OF A RURAL COMMUNITY TO A MOUNTAIN MEADOW,
Colorado E Agricultural Experiment Station, Fort Collins.
K. A. Barbarick, B. R. Sabey, and N. A. Evans.
Journal Water Pollution Control Federation, Vol 54, No 1, p 70-76, January, 1982. 7 Tab, 29 Ref.

Descriptors: *Land disposal, *Wastewater treatment, *Meadows, Effluents, Wastewater, Phosphorus, Sodium, Chlorides, Potassium, *Wastewater irrigation, Irrigation, Crop yield, Hay, Grasslands, *Impaired water use, Colorado, Hayden area.

Changes in the water, soil, and plant properties of a mountain meadow caused by sprinkler application of wastewater effluent or ditch water and the presence of subsurface drainage tiles or natural drainage were investigated. The study was conducted near Hayden, Colorado, at an elevation of 1977 meters, a latitude of about 41 degrees C, and a population of about 1,000. Ranching, farming and coal mining are the main industries of the area. A mountain meadow situated west of the Hayden wastewater treatment lagoons was used for the field study. The soil profile consists of layers ranging from a dark brown, silty clay loam to a mottled gray-brown clay. A gravel lens is encountered at depth of 1.5 to 2.0 meters. The meadow has been used for hay production for at least 10 years and has been flood irrigated continuously during this period. Application of effluent to the meadow produced only a few significant changes in area characteristics. Effluent caused significant increases in the chloride and sodium ion concentrations and uptake of sodium by plants in 1977. Hay yields, protein production and sodium and phosphorus uptake by plants were increased in 1978, and the concentrations of phosphate-phosphorus and exchangeable sodium and potassium in surface soil samples were also increased. Drainage tiles effectively lowered the water table for most of the 1977 irrigation season. The groundwater was below the drainage tiles in most of the 1978 season. Application of the effluent to the meadow for 2 years indicated that no environmental or health hazards resulted. (Baker-FRC)

5F. Water Treatment and Quality Alteration

THE SIDERITE MODEL OF THE FORMATION OF CORROSION-RESISTANT SCALES,
Karlsruhe University (Federal Republic of Germany), Water Chemistry Dept.
H. Sontheimer, W. Kolle, and V. L. Snoeyink.
Journal of the American Water Works Association, Vol 73, No 11, p 572-579, November, 1981. 11 Fig, 1 Tab, 36 Ref.

Descriptors: Corrosion inhibition, *Scaling, *Iron, Water distribution, Water mains, *Corrosion control, Water quality, Siderite, Ferrous carbonate, Calcium carbonate, *Pipes, Water supply systems, Protection, Chemical precipitation.

The concept that siderite ($FeCO_3$) is important in the formation of a protective, corrosion-inhibiting layer in water distribution pipes has led to a siderite model. The model is based on the following reactions: primary--formation of ferrous ion and 2 electrons from elemental iron, formation of hydroxyl ions from water, and formation of carbonates from bicarbonate; secondary--formation of calcium carbonate, ferrous carbonate, and goethite (FeOOH); tertiary--fromation of goethite pseudomorph and magnetite (Fe_3O_4) from ferrous carbonate. Laboratory studies were performed by measuring corrosion rates in steel pipe and by analyzing the chemical composition of the scale. Water from the Karlsruhe, Federal Republic of Germany, distribution system was used. Scales formed from highly buffered water contained 85-90% ferrous iron and 10-15% ferric iron. In slightly buffered water the ferrous portion was 40%. The more ferrous iron in the scale, the better the corrosion protection. The presence of humic acids, calcium ion, and lower oxygen concentrations all increased corrosion protection. although this simplified model cannot explain all observations, it may predict general trends. SPECIFIC AND CHELATE EXCHANGERS: NEW FUNCTIONAL POLYMERS FOR WATER AND WASTEWATER TREATMENT,
Water Purification Associates, Cambridge, MA.
C. Calmon.
Journal of the American Water Works Association, Vol 73, No 12, p 652-656, December, 1981. 2 Fig, 7 Tab, 42 Ref.

Descriptors: *Ion exchange, *Chelation, *Metals, *Water treatment, *Wastewater treatment, *Polymers, Resins, Heavy metals, Anion exchange, Cation exchange, Bactericides.

The 1935 discovery of ion exchange resins has led to development of selective and specific ion exchange materials for water and wastewater treatments. This review presents the characteristics of 21 of these resins. The standard ion exchangers using sulfonic, carboxylic, or amine groups are not selective. All ions are packed up rather than the ones of concern, such as toxic metals. Regenerant costs are high, and selective recovery of ions from effluents is very difficult. Recently developed resins can remove specific metals, such as Hg or Cu, or groups of metals, such as the rare earths. A chelate resin, an insoluble polymer to which is attached a complexing group, involves both ion exchange and chemical reactions. Chelate resins have some limitations. Reaction rates are slower, special operating conditions during elution are required, and high concentrations of elutants may be needed. Recently bactericidal resins have been developed. These rely on (1) the affinity of amino and carboxylic groups in the organisms' tissues for the ion exchange resins, or (2) the presence of a bactericidal agent in the resin. (Cassar-FRC)

THE SEARCH FOR A CORROSION INDEX,
Environmental Science and Engineering, Inc., Gainesville, FL.
J. E. Singley.
Journal of the American Water Works Association, Vol 73, No 11, p 579-582, November, 1981. 3 Fig, 2 Tab, 19 Ref.

Descriptors: *Corrosion index, *Calcium carbonate, *Water quality, Alkalinity, Water distribution, Solubility, *Water mains, Hydrogen ion concentration, *Water supply systems.

A review of corrosion indexes revealed that no general corrosion index is available. It is not likely that a single index can apply to all metals. Some indexes have been applied in inappropriate circumstances. Use of any corrosion index should first be correlated with field test results to determine if it is applicable to a given water. Among the corrosion indexes described are: Langelier (1936), based on the effect of pH on the solubility of calcium carbonate, and a modification by Larson and Buswell (1942); Ryznar's (1944) stability index, with higher numbers indicating a more saturated water; Dye's (1958) momentary excess concept, the casil index, and the aggressive index which accounts for alkalinity. All these methods based on carbonate solubility equations are a measure of solubility of calcium carbonate, not corrosivity. Other methods are based on the ability of water to attack metal pipes and include additional factors. Parameters that must be considered in developing a corrosion index are hardness, alkalinity, carbonate, carbon dioxide, pH, chloride, sulfate, ionic strength, conductivity, total dissolved solids, color, hydrogen sulfide, buffer capacity, phosphate, silica, dissolved oxygen, chlorine, and temperature. THE SCIENTIFIC BASIS FOR CONTROL OF LEAD IN DRINKING WATER BY WATER TREATMENT,
Wiggins Teape Research and Development, Ltd. (England).
I. Sheiham, and P. J. Jackson.
Journal of the Institution of Water Engineers and Scientists, Vol 35, No 6, p 491-515, December, 1981. 8 Fig, 8 Tab, 10 Ref.

Descriptors: *Drinking water, *Lead, Potable water, Heavy metals, *Water treatment, Alkalinity, Acidity, Carbonates, Water supply systems, Water quality.

Work is described which was carried out to identify the factors of water quality which determine lead concentration, to provide the ability to predict the types of water which give rise to excessive lead concentrations, and to define the methods and quality targets for water treatment to minimize lead levels in water. To achieve these objectives, the composition of deposits on the interior walls of lead pipes has been examined, the solubility of lead in water in equilibirum with these deposits has been calculated, and experimental tests have demonstrated the effects of a range of possible methods of water treatment to reduce lead concentrations. The study concludes that lead concentrations in water from lead pipes are limited to a high degree by the solubility of lead in water, and that water treatment can reduce lead levels effectively by ensuring that this solubility is as low as possible. In low alkalinity water, low pH is the predominant cause of high lead concentrations, and pH elevation to about pH 8.5 is required but not generally necessary to increase alkalinity. Addition of orthophosphate is a secondary approach to the treatment of this type of water. For water of high alkalinity addition of orthophosphate is the favored method of treatment, as simple pH adjustment is unlikely to produce a significant decrease in lead concentration. The large increase in pH required to produce substantial reductions in lead levels would have to be preceded by softening or removal of alkalinity, which are subjected to considerable disadvantages. Descriptors: *Information exchange, *Rural areas, *Water quality control, Public relations, Public participation, Public health, Attitudes, Surveys, Publications, Drinking water, *Water supply, Eutrophication, *Vermont, Local governments, Water treatment.

Two experiments in improving the information gap between rural Vermont water consumers and state agencies are described. Mann (1974) used an information display board, a survey of health officers, a health officers' conference, and a 3-month newspaper information compaign. Results indicated that people would take action to assure that their water supply passes minimum standards if they had proper information. A model news release was successful in reporting water quality problems to the public; it required only filling in blanks with the appropriate data. Meetings and training sessions for town health officers significantly reduced errors and problems in sampling water supplies. Neiman prepared two publications to help inform rural water users of water quality problems and solutions. 'A Handbook for Rural Water Users' explains the nature of drinking water standards, reasons for these standards, dangers and results of not meeting the standards, and cost effective alternatives for improving water quality. 'A Layman's Guide to Eutrophication' provides information on one of the subjects least understood by town officials. Obstacles to improvement of rural water supplies were lack of information exchange between local officials and consumers, fragmentation of agencies into diverse departments, and public apathy. CONSIDERATIONS ON ORGANIC MATTER IN DRINKING WATER TREATMENT,
Municipal Water Works of Rotterdam (Netherlands).
J. J. Rook, A. Graveland, and L. J. Schultink.
Water Research, Vol 16, No 1, p 113-122, January, 1982, 6 Fig, 5 Tab, 3 Ref.

Descriptors: *Organic matter, *Chlorinated hydrocarbons, *Activated carbon, *Water treatment, Drinking water, Design criteria, Surface water, *Netherlands, Performance evaluation, Organic carbon, Water quality, Ozonation, Chlorination, Adsorption, Water treatment facilities.

The efficiency of organic matter removal was evaluated in four water treatment systems in the Netherlands. All systems used stored surface water as the raw water source. Performance varied according to the parameters chosen. Most groups of parameters gave incomplete information. The classic parameters, COD, permanganate, ultraviolet extinction, and color, may give false impressions of removal efficiencies when oxidative treatments are involved. The instrumental total organic carbon (TOC) method is the most reliable in this group. The parameters, taste, color, and odor, also give limited information on water quality. A method for determining biodegradable organic matter (AOC) introduced by van der Kooy (1978) is the best parameter to judge efficiencies of water treatment chains from the bacteriological aspect. Toxic material parameters include chlorinated organic compounds and organically bound chlorinated compounds adsorbable on activated carbon (AOCl). In designing drinking water treatment trains, water should have minimum: (1) taste and odor, determined by organoleptic means, (2) toxic substances, determined by halogenated organic compounds (AOCl), and (3) bacterial count, determined by the AOC test and 22 C bacterial counts. This procedure helps avoid overtreatment. Parameters (bacterial counts, AOC, trihalomethanes, and AOCl) are given for the four treatment systems: (1) prechlorination plus granular activated carbon, Rhine River and polder water, (2) prechlorination and powdered activated carbon, Meuse River, (3) ozonation and biological filtration, highly colored water, and (4) ozonation and granular activated carbon, Meuse River, (Cassar-FRC)

GRANULAR ACTIVATED CARBON INSTALLATIONS,
Culp/Wesner/Culp, Cameron Park, CA.
R. L. Culp, and R. M. Clark.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-102492, Price codes: A13 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-177, October, 1981. 9 p, 1 Fig, 1 Tab.

Descriptors: *Activated carbon, *Water treatment, *Cost analysis, *Drinking water, *Adsorbents, Wastewater treatment, Reactivation, Odor control, Color removal, Organic compounds.

On January 9, 1978, EPA proposed the use of granular activated carbon (GAC) as a means of treating drinking water. Questions have been raised regarding EPA's cost estimates for GAC use. As part of studies designed to establish water supply unit process costs, GAC treatment design criteria, performance, and cost data were compiled from 22 operating municipal and industrial GAC installations that treat water and wastewater, and that process food and beverage products. Results indicate that a substantial number of GAC installations have been operating successfully for many years. Although long-term use of GAC and powdered activated carbon by municipal waterworks and industries has been widespread, no adverse health effects have been reported. GAC treatment of public water supplies to remove trace organics is fairly new, but GAC treatment of public water supplies for taste and color control or for color removal is practiced in about 46 cities in the US. Pilot plant testing of GAC adsorptive and reactivation characteristics in municipal water treatment plants can be combined properly with the known costs of GAC systems in wastewater treatment to yield a design basis and preliminary cost estimates that are satisfactory for developing water treatment projects. EFFECT OF HALOGENS ON GIARDIA CYST VIABILITY,
Oregon Univ. Health Sciences Center, Portland.
E. A. Meyer.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-102294, Price codes: A02 in paper copy, A01 in microfiche. Environmental Protection Agency Project Summary EPA-600/S2-81-174, October, 1981. 3 p, 2 Ref. R-806032.

Descriptors: *Giardia, *Disinfection, *Drinking water, *Water treatment, *Chlorination, *Iodine, Water temperature, Hydrogen ion concentration, Protozoa, Parasites, Halogens.

The vehicle for spreading epidemic giardiasis is drinking water. The development of a method to induce the excystation of Giardia cysts has made possible, for the first time, a reliable method of determining Giardia cyst viability, and thus, the ability to determine whether a given procedure kills these cysts. Using this method, the effects of halogens on thee cysts of G. lamblia were tested. In one set of experiments, chlorine was tested under a variety of conditions including chlorine concentrations, temperature, pH, and chlorine-cyst contact time. Within the range of variables studied, the ability of cysts to excyst after treatment was affected by each of these variables. Percent excystation decreased with: increasing chlorine concentration; increasing temperature; decreasing pH; and increasing contact time. In a second set of experiments, six small-quantity water disinfection methods were tested. Two methods (Halazone and bleach) employed a form of chlorine, and four methods (Globaline, EDWGT, and elemental iodine in tincture and in saturated form) involved some form of iodine. Halazone and EDWGT inactivated all of the cysts under all test conditions. Bleach, Globaline, and tincture of iodine only failed to inactivate all cysts under one set of conditions: in clear water at 3 C. Saturated iodine failed to inactivate all of the cysts in either clear or cloudy water at 3 C, but inactivated all cysts at 20 C. (Moore-SRC)

COAGULATION MECHANISMS: AN ELECTRON MICROSCOPIC STUDY USING ALUMINUM SULFATE,
Yamanashi Univ., Kofu (Japan). Dept. of Environmental Engineering.
T. Ishibashi.
Journal of the American Water Works Association, Vol 72, No 9, p 514-518, 1980. 8 Fig, 9 Ref.

Descriptors: *Turbidity, *Water treatment, Drinking water, Potable water, *Coagulation, Clays, *Aluminum sulfate, Zeta potential.

A transmission electron microscopic study was performed to obtain visual data on the mechanism of coagulation. The findings call into question the validity of the double-layer theory of coagulation on clay colloid. Shokozan clay, classified mineralogically as dickite clay, was selected for the study. After the clay solution settled for 24hr, microscopic inspection revealed particles several micrometers in diameter among the particles remaining in suspension. Further treatment of the suspension was rendered. The primary stage of coagulation of the clay colloid was reached by adsorption of soluble aluminum hydrolysis ions and by the chemical reactions producing aluminum hydroxide on the surface of the clay particles. The coagulation could be carried out at a zeta potential of -26.6 mV, much lower than the typical values reported in the literature, suggesting that coagulation was not directly related to the zeta potential value. At this low dosage of alum the coagulated particles and the uncoagulated particles coexisted in the suspension. Adsorption and chemical reactions between soluble aluminum hydrolysis ions and the surface of clay particles seem to be completed instantaneously after the alum dosing. Whether aluminum hydroxide is formed in films on the colloids or on independent particles may have a significant effect on the floc growth. The double-layer theory holds that the zeta potential and the colloid stability are correlated, and that a sufficient reduction of zeta potential is needed to achieve coagulation. In this study coagulation was carried out even with high zeta potential, indicating that adsorption of potential determining ions and bridging explain the observed phenomena better than the double-layer theory. COAGULATION: EXPERIENCES IN ORGANICS REMOVAL,
Minnesota Univ., Minneaplis. Dept. of Civil and Mineral Engineering.
M. J. Semmens, and T. K. Field.
Journal of the American Water Works Association, Vol 72, No 8, p 476-483, August, 1980. 17 Fig, 1 Tab, 10 Ref.

Descriptors: *Water treatment, *Coagulation, Organic compounds, Trihalomethanes, Sludge, Alum, Acidity, Temperature effects, Flocculation, Sampling, *Mississippi River, *Minneapolis, Minnesota.

Coagulation tests were run of water samples taken from the Mississippi River close to the point of extraction for the Minneapolis water treatment plant. The water is high in organic content, with dissolved organic carbon concentrations ranging between 10 and 16 mg/liter during the course of the study. Turbidity ranged between 2 and 25

NTU. The coagulation process with alum as the sole coagulant was found to be capable of achieving significant organics removal from the Mississippi River water. The removals were found to be strongly pH and dose dependent. Organics absorbing ultraviolet light are removed more effectively by coagulation. Tests conducted on unconcentrated and reconstituted Mississippi River water at various times indicate that the organics removal was very reproducible. The only significant variation was noted when low alum doses were used in high turbidity waters. The influence of varying flocculation times on turbidity and organics removal was examined for three river water samples. Tests were also conducted to determine whether the organics removal performance could be improved by altering the way in which the coagulant was added to the river water. The results essentially indicated that there was no benefit to a two-stage coagulation process. Similar results were obtained with the three- and four-stage studies. The recycling of sludge to supplement an alum dose did not improve organics removal compared to controls receiving no recycled alum sludge. It was concluded that the most important variables influencing organics removal by alum coagulation are alum dose and pH. (Baker-FRC)

CONTROL OF TRIHALOMETHANES IN DRINKING WATER,
Louisville Water Co., KY.
D. T. Duke, J. W. Siria, B. D. Burton, and D. W. Amundsen.
Journal of the American Water Works Association, Vol 72, No 8, p 470-476, August, 1980. 5 Fig, 5 Tab.

Descriptors: *Drinking water, *Organic compounds, Water quality, *Water treatment, Potable water, *Trihalomethanes, Activated carbon, Hydrogen peroxide, Chlorination, Ammonification, Ammonium.

The implementation of effective methods for the control of trihalomethanes (THM) is neither impossible nor overly difficult. Methods such as ammoniation for hindering THM increases after chlorination have been explored and the technology is available, as is the technology for other methods of disinfecting water supplies without forming significant amounts of THMs. While these do pose an inevitable cost problem, they also present solutions to the major problem. Each plant must survey its individual needs for THM control and select the most appropriate technology for the job. One test that has been widely used to study the effect of chlorination on source waters is the trihalomethane formation potential test (THMFP). Temperature, pH, chlorine dosage and chlorine contact time are the critical factors in this test. Since chlorine contact time is critical in THM formation, a system that reduces this contact time may feasibly reduce THM formation. The THMFP of the source water increases as the temperature of the water increases, peaking during the summer months. Use of ammoniation in place of chlorination offers an effective means of reducing THM growth. The use of chloramines, ozone, and hydrogen peroxide as disinfectants that do not form THMs should also be considered. Hydrogen peroxide, a dechlorinating agent, when used in conjunction with chlorine might provide the right combination to achieve complete disinfection and prevent THM formation simultaneously. The cost of chemicals for this treatment would be significantly higher than for ammoniation, but the results are much more successful. Suggested use of granular activated carbon pertains to a wider scale removal of organic compounds than just THMs. (Baker-FRC)

THE MONOCHLORAMINE-GAC REACTION IN ADSORPTION SYSTEMS,
Illinois Univ. at Urbana-Champaign. Dept. of Environmental Engineering.
B. R. Kim, and V. L. Snoeyink.
Journal of the American Water Works Association, Vol 72, No 8, p 488-490, August, 1980. 3 Fig, 11 Ref.

Descriptors: *Adsorption, *Activated carbon, Granular activated carbon, Simulation, Model studies, Water treatment, Drinking water, Potable water, *Chlorination, Organic compounds, *Monochloramine, Chemical reactions.

This paper deals with the reaction kinetics of monochloramine, a critical component of chlorine residual, with granular activated carbon. The results show the effect of influent concentration, flow rate, contact time, and carbon particle size on the GAC-ammonium chloride reaction. Monochloramine reacted slowly with GAC by comparison to the rates at which free chlorine and dichloramine react. After an acclimation period, the effluent ammonium chloride concentration from a GAC contactor reaches a steady state value if such influent conditions as ammonium chloride concentration, flow rate and other factors do not change. The reaction rate at steady state is slower than the initial rate. At steady state the reaction rate for ammonium chloride is very slow if the solution concentration is below about 1 mg/liter as chlorine. Very long contact times are therefore required if the concentration is to be reduced below detectable levels. (Baker-FRC)

EVALUATION AND TREATMENT OF SYNTHETIC ORGANICS IN DRINKING WATER SUPPLIES,
Montgomery (James M.), Pasadena, CA.
R. R. Trussell, and A. R. Trussell.
Journal of the American Water Works Association, Vol 72, No 8, p 458-470, August, 1980. 21 Fig, 5 Tab, 51 Ref.

Descriptors: *Water supply, *Organic compounds, Pollutant identification, *Drinking water, Potable water, *Water treatment, Reulations, Evaluation, Reviews, *Synthetic organics.

An approach is outlined which a water utility might employ to evaluate the purity of its water source, review the effectiveness of its current treatment, assess the exposure of the consumer to risks, study the feasibility of various courses of action, and implement a final plan. The task of dealing with synthetic organics can be divided into six parts: source evaluation, risk assessment, feasibility analysis, scheduled periodic surveillance, cost-benefit analysis, and implementation. Tasks required to evaluate the integrity of the quality of a water source are the source survey and the source analysis. Once source evaluation is complete, an assessment must be made of the health risk imposed on the population consuming the water. Potential synergistic and antagonistic effects must be considered between different compounds. If the results of the source evaluation and risk assessment are not satisfactory, a feasibility study must be conducted to determine the most effective means of providing a safe water supply. Five basic alternatives may be considered if the water supply is not adequately protected: find a protected source; eliminate the contaminants; use a combination of off-line storage with river supplies so that water can be drawn off during periods of good quality; treat the water supply to remove the materials of concern; and install dual distribution systems and use water from a protected source for domestic supply and water from the unprotected source for less exacting uses. Treatment may include aeration, coagulation, oxidation, biological processes and adsorption. (Baker-FRC)

REMOVAL OF TOTAL ORGANIC HALOGEN BY GRANULAR ACTIVATED CARBON ADSORBERS,
Illinois Univ. at Urbana. Champaign. Dept. of Civil Engineering.
J. E. Quinn, and V. L. Snoeyink.
Journal of the American Water Works Association, Vol 72, No 8, p 483-488, August, 1980. 14 Fig, 3 Tab, 6 Ref.

Descriptors: Water quality, *Organic carbon, Adsorption, *Activated carbon, *Halogens, Hazardous materials, *Water treatment, *Monitoring, Drinking water, Potable water, Water supplies.

This study was undertaken to show the potential for using total organic halogen (TOX) measurements to determine the degree of saturation of activated carbon adsorbers. Humic substances, a major constituent of natural waters, were chlorinated and applied to laboratory columns for this purpose. Samples taken at several times from experimental adsorbers at Jefferson Parish, Louisiana, were also evaluated. The results of the study showed that for these adsorbates TOX buildup on the carbon was gradual and consistent, and that measurement of the TOX profile in the adsorber at different times can be used to determine when the adsorption capacity has been depleted and replacement or regeneration is needed. Determination of the TOX profiles at Jefferson Parish showed a gradual saturation of adsorption capacity at all depths with time. Thus it appears that measuring the group parameter total organic halogen may be an acceptable alternative to analyzing specific compounds in order to monitor water quality and the efficiency of water treatment processes for removing potentially hazardous organics. EFFECTS OF CHLORINE CONCENTRATION ON THE STRUCTURE OF POLIOVIRUS,
New Mexico State Univ., Las Cruces. Dept. of Biology.
M. E. Alvarez, and R. T. O'Brien.
Applied and Environmental Microbiology, Vol 43, No 1, p 237-239, 1982. 1 Fig, 4 Ref. OWRT-A-066-NM.

Descriptors: *Viruses, *Chlorination, Wastewater treatment, *Water treatment, Chemical reactions, Poliovirus.

Relationships are explored between chlorine concentration, loss of viral infectivity and viral composition in aqueous medium changes. Poliovirus type 1 (Mahoney) was used in the study. At chlorine concentrations up to 0.4 mg/liter, there were no major changes in the poliovirus sedimentation coefficients, although virus inactivation was 38%. At chlorine concentrations of 0.8 mg/liter or higher, there was a shift of the virus sedimentation coefficients from the 156S value associated with intact particles to 80S, which was shown to represent structures lacking RNA. The percentage of counts associated with empty capsid peaks did not correlate with percent inactivation values. These results indicate that changes in virus composition and structure are dependent on the initial chlorine concentration and that these changes are not the primary cause of virus inactivation. Chlorine concentrations in excess of 0.8 mg/liter apparently lead to reactions within the virus particles which can result in separation of the viral components. (Baker-FRC)

WATER IN PHARMACEUTICALS AND COSMETICS INDUSTRIES,
Chiltern Water Treatment Co. (England).
R. W. Hill.
Effluent and Water Treatment Journal, Vol 21, No 11, p 515-517, 1981. 1 Fig, 2 Tab, 14 Ref.

Descriptors: *Water quality, *Industrial water, *Water treatment, Reverse osmosis, Filtration, Membrane processes, Standards, Bacteria, Water use, *Pharmaceutical industry, *Cosmetic industry.

The treatment of water which appears in the products of the cosmetics or pharmaceuticals industries is discussed. In the British Pharmacopoeia two categories are specified for water used by the pharmaceutical industry, purified water and water for injections. The major difference between these two categories is that purified water refers to chemical impurities, while water for injection must also be free of biological contaminants. With the exception of injection and infusion solutions, other products will be exposed at some time to the atmosphere and thus to possible biological contamination. It is usually necessary to use purified water even for apparently non-critical cosmetics because contaminants may interfere with the manufacturing process or cause deterioration in the

LIBRARY U. OF I. URBANA-CHAMPAIGN

appearance of the product. Ion exchange is fast becoming the most common method of preparing purified water on the commercial scale. Reverse osmosis is able to remove non-ionized contaminants and is becoming increasingly popular. However, this method alone will not usually effect sufficient removal to meet purified water requirements, and it is usual to employ a mixed bed ion exchange polishing unit downstream. Reverse osmosis can be used for producing sterile water, but there is some recent evidence that certain small bacteria, viruses and pyrogens can pass through the semipermeable membranes. Storage of high purity water is difficult, as this substance is an exceptionally good solvent. Care must be taken in selecting construction materials for purified water systems. Polishing filters should be employed at the points of use whenever possible. (Baker-FRC)

THE NECKAR AS A SOURCE OF PROCESS AND RESERVE WATER (DER NECKAR ALS LIFEFERANT VON BETRIEBS- UND RESERVEWASSER),
Technisch Werke der Stadt Stuttgart (Germany, F.R.).
K. E. Oehler.
GWF-Wasser/Abwasser, Vol 122, No 12, p 566-571, 1981. 2 Fig, 5 Tab. English Summary.

Descriptors: *Water supply, *River water, *Municipal water, Water quality, Neckar River, *Stuttgart, Germany, Impaired water use, Ammonium, Process water, Industrial water, Water distribution, *Water treatment, Potable water, Drinking water, Chlorination.

Following completion of the Lake Constance drinking water supply for the city of Stuttgart, the Berg water treatment plant on the Neckar River was kept in operation to supply industrial process water, to serve as an emergency supply for the city if needed, and to reduce the demand on the piped supply. Berg water is used in a power plant, the gas plant, the city laundry, the railway, the parks and fountains of the city, and municipal air conditioning facilities. The quality of Neckar water is still monitored regularly. The principal problem pollutants in the Neckar at present are high ammonium concentrations and trihalomethanes. Detailed analyses of chemical composition for 1980 revealed significant changes only during extremely high and low flow. During high flow sludge transport was noted, and enrichment of wastewater constituents occurred during low flow. Nevertheless most water quality parameters still fell within the highest quality class, except for phosphate and ammonium concentrations. The water treatment of the Neckar supply comprises sub-breakpoint chlorination, aluminum sulfate flocculation, settling and rapid filtration. Powdered activated carbon, slow sand filtration and charcoal filtration are used only in the case of drinking water. Low-level chlorination is the final step. This simplified treatment and the short distribution pathways make it possible to supply the process water at half the cost of normal drinking water. (Carroll-FRC)

PURIFICATION OF SURFACE WATERS (REINIGUNG VON OBERFLACHENWASSER),
Boliden-Knapsack G.m.b.H., Hurth-Knapsack (Germany, F.R.).
G. K. Kohler.
Wasser, Luft und Betrieb, Vol 25, No 11, p 10-12, 1981. (No English Summary).

Descriptors: *Water treatment, *Drinking water, *Filtration, Flocculation, Chemical coagulants, Flotation, Separation techniques, Magnetic separation, Phosphate removal, Surface water, Tegeler Sea, *Berlin, Germany.

Increasing demands for water necessitate the use of increasing amounts of surface water for drinking water preparation. Numerous studies have been conducted on improved methods for surface water treatment, including especially flocculation. Phosphorus removal is a major goal of flocculation and of combined chemical precipitation and filtration. The use of a two-filter system with a second flocculation step between the filters greatly improves phosphate removals. Including a container flocculation step before the filter increases filter life and phosphate retention without excessive chemical addition. This system was applied to cleanup of water obtained from the heavily contaminated Tegeler Sea near Berlin. Sludge retention was a substantial problem during the trial runs. Tube flocculation could markedly increase floc removal efficiency. Magnetic flocculation is another possibility for increasing flocculation efficiency. Flotation may be preferable to flocculation in special circumstances. Nevertheless available systems are not yet perfect in efficiency. (Carroll-FRC)

SELECTIVE REMOVAL OF FLUORIDE, ARSENATE AND PHOSPHATE IONS FROM WATER (SELEKTIVE ENTFERNUNG VON FLUORID-, ARSENAT- UND PHOSPHAT-IONEN AUS WASSER),
Institut Fresenius, Chemische und Biologische Laboratorien GmbH, Taunusstein-Neuhof (Germany, F.R.).
W. Fresenius, and W. Schneider.
Wasser Luft und Betrieb, Vol 25, No 11, p 14-15, 1981. 12 Ref. (No English Summary).

Descriptors: *Water treatment, *Fluoride, *Adsorption, Aluminum oxide, Arsenic compounds, *Phosphate removal, Drinking water, Hydrogen ion concentration, Aluminum compounds.

Available waters in some localities exceed the maximum permissible levels for fluoride, phosphate and arsenate, and therefore require treatment prior to consumption as drinking water. Special grades of aluminum oxide were developed as fluoride adsorbents and tested in a pilot scale installation. Residual fluoride contents below 1 mg/1 were obtained using initial waters with fluoride contents of 3 mg/1 and 10 mg/1 and pH values of 6.3-6.5. Filter lifetimes were about 30 days. About 10 liters of 2 N sodium hydroxide per kg aluminum oxide were required for regeneration. Accumulation of fluoride by the adsorbent from the rinse water can be prevented by using rinse water with pH values in excess of about 7.5. Fluoride ion removal is not selective, but hydrogen arsenate and hydrogen phosphate are also removed to a high degree. Changes in other mineral constituents were not observed. The increase in aluminum content in the filtered water samples amounted to about 0.1 mg/l. (Carroll-FRC)

In designing the Abub Shahar water treatment demonstration plant in India, the lack of skilled staff and possibility of discontinuous terminal chlorination were taken into account. The filters function mainly for polishing and bacterial purification. Raw water in a storage tank is filtered 24 hr per day by four circular filters with one as a standby. The filtered water is chlorinated and held in two clearwater tanks until distribution to the rural villages. The Abub Shahar village demonstration plant has experienced vagaries of electric power supply since it began operation in June of 1979. Although backup diesel generators can be used, extra capacity capabilities could be supplied to the plant's different units to satisfy about 66% of design demand during these adverse periods. The backup filter is being operated constantly, and the high-level tank lacks a float valve on the outlet. A partially above ground filter would have been more appropriate to facilitate scouring of supernatant water. A master sluice valve to control raw water pumping and overflows in all the filters are suggested to improve flow regulation. A separate supernatant scour-out box combined with filter overflow and a modified outlet arrangement incorporating rate-limiting and measuring orifices in the backfilling pipe are also proposed. (Geiger-FRC)

FLOCCULATION IN PIPES FOR WATER POLLUTION CONTROL AND PHOSPHORUS REMOVAL PURPOSES (UBER DIE ANWENDUNG DER FLOCKENBILDUNG IN ROHREN ZUR WASSERREINHALTUNG UND PHOSPHATELIMINATION),
Bundesgesundheitsamt, Berlin (Germany, F.R.). Inst. fuer Wasser-, Boden- und Lufthygiene.
A. Grohmann.
Zeitschrift fur Wasser und Abwasser Forschung, Vol 14, No 5/6, p 194-209, 1981. 15 Fig, 3 Tab, 16 Ref.

Descriptors: *Water treatment, *Flocculation, *Design criteria, Wastewater treatment, Water treatment facilities, Laboratory studies, Separation techniques, Chemical coagulation, Pilot plants, *Phosphate removal, Industrial wastewater, *Water pollution control.

The possibility of performing flocculation in pipes offers a means of significantly accelerating the flocculation process, since the velocity gradients in pipes enhance agglomeration of microflocs. A pipe length of 40 m will allow an adequate safety margin for maintenance of flocculation, since a steady state of floc growth versus breakup is reached in approximately 20 m. Adequate colloid and precipitation products destabilization is required. In addition to rising velocity gradients, addition of anionic polyacrylamides will also increase floc size. The design selected must provide sufficient turbulence to bring microflocs into contact with one another, but not to destroy flocs already formed. Design and operation data are presented for a trailer-mounted water treatment pilot plant and an industrial water treatment plant. Data are also tabulated for pipe flocculation systems ranging from laboratory tests with model colloids to full-scale water and wastewater treatment plants. Pipe sizes ranged from 8 to 600 mm diameter. Typical values obtained were flocs of 2-3 mm with a settling rate of 10 m/hr and a residual turbidity (after 10 min standing) of 1.5 formazin units, at an anionic polyacrylamide addition rate of 0.5 g/cu m and a mean flow velocity gradient of 70/sec. TANZANIA'S MASTER WATER PLAN WILL MISS DECADE GOAL,
R. Laishey.
Water, No 42, p 26-27, 1982.

Descriptors: *Developing countries, *Water supply development, Potable water, Drinking water, Water supply, *Tanzania, Shallow wells, Wells.

In 1977, 90% of the rural population of Tanzania was living in village settlements, and the government was attempting to supply them with safe potable water. The country had announced an ambitious water plan in 1977, with a target date of 1991 as the year by which all the rural population would be within 400 meters of safe potable water. In 1973 the first phase of the scheme began, with the drawing up of a master plan for each of the 20 regions of the country. By the beginning of the 1980s, 12 regions were equipped with paster plans, another five were under preparation and for three no plans had yet gotten underway. A Master Plan Coordination Unit was established to oversee the project and gather the needed funding. Officially some six to seven million people or just under 40% of the rural population are now within 400 meters of potable water. In reality the figure may be closer to three to four million. Part of the problem is cost. Experiments are being conducted with cheaper technologies and self-help schemes. It is believed that the shallow well scheme can reach some 50% of the population in rural areas, but shallow wells have serious drawbacks. One well can probably only efficiently serve a village of 1,500 people. Many villages have 2,000 or more people. (Baker-FRC)

COLLOIDAL ORGANICS,
Williamsport Sanitary Authority, PA.
M. H. Gerardi.
Public Works, Vol 113, No 2, p 65-67, 1982. 2 Fig, 8 Ref.

Descriptors: *Colloids, *Organic matter, Decomposing organic matter, Litter, Taste, *Water treatment, *Water quality, Odor control, Odor-producing algae, Odors, Coagulation.

Relatively high concentrations of organic colloids in a water supply are troublesome and should be removed for the following health and esthetic reasons: taste and odor problems are largely due to colloidal organics, byproducts of algae, diatoms, and actinomycetes, which produce objectional tastes and odors; humic and fulvic acids are precursors of chloroform; colloidal organics produce undesirable colors in water; colloidal organics cause fouling of anion exchangers and interfere with the demineralization of water; metal complexes of organic colloids strongly influence metal distribution between the dissolved and particulate state; the presence of colloidal organics can shield waterborne pathogens from disinfection treatment and can create problems associated with biological quality of treated water; and colloidal organics interfere with oxidation and removal of iron and manganese from water. Most organic substances produced by plants and animals in lakes and rivers and those brought there from the outside, such as leaf litter, are eventually decomposed through the metabolism of various aquatic organisms such as bacteria and fungi. Since the electrically charged surfaces of colloidal particles cause them to repel one another and maintain the stability of a colloidal dispersion, neutralization of the charged surfaces would permit the colloidal particles to come together and be removed from a water supply. The removal of colloids in this manner can be accomplished by coagulation. Various hypothetical models have been proposed to explain the destabilization and initial aggregation of colloidal matter by the addition of coagulants. (Baker-FRC)

YEAR-ROUND DISTRIBUTION SYSTEM MAINTENANCE,
Connecticut Water Co., Clinton.
J. E. Lebert, Jr.
Journal of the New England Water Works Association, Vol 95, No 4, p 267-270, December, 1981.

Descriptors: *Water conveyance, *Maintenance, Water distribution, *Water mains, Water supply systems, Management planning, Materials, Iron, Corrosion, Saline water, *Guilford-Chester Division, Connecticut Water Company, *Connecticut.

A review is presented of the last 15 years of year round distribution system maintenance carried out by the Connecticut Water Company, Guilford-Chester Division. During this time over 37,000 feet of 2, 4 and 6 inch cast iron and galvanized iron main was replaced with 8 inch or larger ductile iron mains. All new water mains in the salt water areas have been transilwrapped for protection. Larger mains have provided greater fire protection and a better quality of water, as they are all cement lined. Many dead ends were also tied in to improve fire protection and quality. Every service on the replacement mains was also replaced with copper tubing or plastic tubing. Crew size has been kept low, primarily due to the replacement vs repair program. Work is very seldom interrupted to make an emergency repair. A winter and spring maintenance program has been devised to make the best use of the time available. A program of replacing or repairing bridge crossing, culvert crossings, and river crossings has also been started. The policy aims at repairing or replacing before a problem occurs. (Baker-FRC)

REACTION OF OZONE WITH TRANS,TRANS-MUCONIC ACID IN AQUEOUS SOLUTION,
Kernforschungszentrum Karlsruhe G.m.b.H. (Germany, F.R.). Inst. fuer Radiochemie.
E. Gilbert.
Water Research, Vol 14, No 11, p 1637-1643, November, 1980. 8 Fig, 3 Tab, 13 Ref.

Descriptors: *Ozone, *Organic compounds, *Oxidation, *Water treatment, Aromatic compounds, Muconic acid, Peroxides, Chemical degradation, Degradation products, *Ozonation, Drinking water, Chemical reactions, Phenols, Kinetics.

Ozonation of trans,trans-muconic acid in aqueous solution at pH 3 leads to the formation of fumaric acid aldehyde, glyoxal, glyoxylic acid and formic acid. As the reaction progresses, these are oxidized to the stable end products oxalic acid, mesoxalic acid and carbon dioxide. Hydrogen peroxide has been observed, in addition to unstable organic peroxides. Organic peroxides are not observed in the case of ozonation at pH 7-8, and the amounts of organic peroxides formed in this case are smaller than at pH 3. Up to the point of complete elimination of muconic acid the specific ozone consumption was 3.2 mmol ozone per mmol acid. Quantitative analysis of the oxidation products indicated that the ring opening products initially formed are further oxidized during ozonation, resulting in very low steady state concentrations in the course of ozonation at high ozone doses and low initial concentrations of aromatics to be oxidized. STRATEGIES TO CONTROL NONPOINT SOURCE WATER POLLUTION,
Duke Univ., Durham, NC. Dept. of Civil Engineering.
J. J. Peirce.
Water Resources Bulletin, Vol 16, No 2, p 220-225, April, 1980. 1 Tab.

Descriptors: *Water pollution control, *Nonpoint pollution sources, Regulations, Environmental management, *Regional planning, Planning, Water quality control, Management, Water policy, Research priorities, Monitoring, New York, Virginia, Wisconsin, Urban runoff.

Strategies for nonpoint source water pollution control are discussed for three representative states, Virginia, New York, and Wisconsin. The most significant nonpoint pollution source in these states is urban storm water runoff, including combined sewer overflows. Others are silviculture activities, construction, mining activities, on-site wastewater treatment facilities, disposal of municipal and idustrial sludge and refuse, and agricultural runoff. A complete range of control strategies is illustrated, from voluntary compliance to strict regulations. Virginia favors voluntary action, Wisconsin plans to implement strict regulations if voluntary compliance is ineffective, and New York favors voluntary compliance combined with some regulations. A study of the programs and agencies in these states indicates: (1) nonpoint sources of pollution are a major component of overall water pollution, (2) technology exists to control these problems, (3) present control programs are not always technologically sound or cost effective, and (4) existing control programs will work only if meaningful actions take place in the future (voluntary compliance and effective implementation of regulations). Zeitschrift fur Wasser und Abwasser Forschung, Vol 14, No 5/6, p 180-187, 1981. 9 Fig, 4 Tab, 7 Ref.

Descriptors: *Watershed protection, *Reservoirs, *Phosphate removal, *Fish ponds, Adsorbents, Activated alumina, Filtration, Impoundments, Nonpoint pollution sources, Aluminum compounds, Nitrification, Ammonium, Receiving waters, Germany.

Fish ponds can represent significant sources of pollutants, especially phosphorus compounds and ammonia, in receiving waters. In 1987-1980 a hatchery located on the Derenbach introduced 55-65 kg of total phosphorus per year into an impounding reservoir located on the Wahnbach, contributing significantly to algal growth in the reservoir. Gravity filtration units were designed and inserted in the fish pond effluent line. The filters had a total surface area of 24 sq m and contained 19.8 metric tons of activated alumina. Filtration speed was conrolled to achieve satisfactory phosphate elimination and ammonium removal by nitrification. Filters were back-washed every 4 weeks with pond water; the back-wash water and sludge were returned to the main pond. Over the 10-month operation period, average orthophosphate removals of 83% were achieved, and average total phosphate removals of 77%. The effluent orthophosphate concentration was approximately equal to the desired value of 50 microg/liter. About 40% of the total organic carbon was also removed. Unexpectedly high ammonium ion removals were also attained, ranging up to 90%. No increase in aluminum level was recorded in the effluent. lgal clogging of the filter can be reduced by excluding light. Operating costs were estimated at 0.05 German Marks per cu m of filtered water. The filtration unit is still operating satisfactorily after one year. (Carroll-FRC)

WATER-QUALITY PROBLEMS AND MANAGEMENT OF AN URBAN WATERFOWL SANCTUARY,
Wisconsin Univ. Green Bay. Coll. of Environmental Science.
H. J. Harris, Jr., J. A. Ladowski, and D. J. Worden.
Journal of Wildlife Management, Vol 45, No 2, p 501-507, 1981. 8 Fig, 22 Ref.

Descriptors: *Ponds, *Eutrophication, Nutrients, Birds, Water birds, *Waterfowl, *Water pollution sources, Wildlife habitats, Wildlife, Wildlife conservation, *Beach Wildlife Sanctuary, Green Bay, Wisconsin, *Water quality control.

The effects of waterfowl on water quality of an urban waterfowl sanctuary and the effectiveness of dredging as a renovation technique were investigated. The study was conducted at the Bay Beach Wildlife Sanctuary, Green Bay, Wisconsin. The sanctuary is a complex of interconnected manmade ponds surrounded by urban open space, including wetlands. Sources of water for all ponds are rain, runoff, and groundwater, with no connection between the ponds and Green Bay. Waterfowl use was estimated by direct counts several times a month over a 4 year period, usually taken at the time of water sampling. There were large differences in intensity of waterfowl use between the two ponds selected for study, one of which (N) was dredged, while the other (L) served as control. The estimated average annual use of N over a 4 yr period was 180,000 waterfowl days, whereas the use of L was 31 waterfowl days. Calculated annual loading from waterfowl in N amounted to 378 kg of total phosphate, 378 kg total nitrogen, and 7,830 kg of total solids. For L, comparable fiures were 0.065 kg phosphate, 0.065 kg total nitrogen, and 1.35 kg total solids. A sharp decrease in total phosphate and nitrate-nitrogen was noted in N the year following dredging. A marked decline in chlorophyll a was also noted in N after dredging and was correlated with decrease in the number of phytoplankton units/liter of water in the year following dredging. Diversity of phytoplankton, however, increased. While it may be assumed that waterfowl act as a nutrient source and bring small ponds to eutrophication, the key finding of this study was that eutrophication can and does occur rapidly under certain conditions. This is critical in the design and operation of waterfowl urban sanctuaries. (Baker-FRC)

AERATION CHARACTERISTICS OF FLOW RELEASE CONTROLS ON ILLINOIS WATERWAY DAMS,
Illinois State Water Survey, Urbana.
T. A. Butts, and R. L. Evans.
Circular 145, 1980. 69 p, 7 Fig, 24 Tab, 18 Ref, 7 Append.

Descriptors: *Dams, *Flow control, *Reservoir releases, *Dissolved oxygen, *Aeration, *Spillway gates, Discharge coefficient, Water quality, Weirs, Locks, Flow measurement, Spillways, Diversion, On-site data collections, *Water quality control, *Illinois waterway dams.

One of the most obvious and direct effects dams have on water quality is the creation of abrupt changes in dissolved oxygen (DO) concentrations. This study's main objectives were to gather physical and chemical data for use in a dam aeration calibration procedure based on a weir formula developed in Great Britain, and to evaluate the effects of increased Lake Michigan diversion water on the dam aeration characteristics. On-site DO and temperature measurements were taken above and below flow release structures and in calibrated weir boxes at seven dams. Water flowing over weirs or through head-loss control structures, such as Tainter and sluice gates, can be aerated or deaerated depending upon the ambient upstream DO concentration. Smaller gate openings consistently had greater reaeration capacities (approximately twice the oxygen transfer efficiency) than larger openings, i.e., the aeration efficiency is inversely related to opening size. This means more efficient aeration could be achieved by using the smallest opening possible while maintaining a desired downstream flow. For example, if 8 feet of opening is required at Starved Rock, 8 gates opened at one foot would be better than two gates at 4 feet, or two at 3 feet and one at 2 feet. However, dam aeration coefficients derived varied significantly within a dam, depending on the mode of operation, and varied greatly between dams. It was determined that under current operating modes the aeration capabilities of the flow release structures at the dams above the LaGrange and Alton pools will be significantly lowered by increasing diversion to 10,000 cfs. COVERING BOTTOM SEDIMENTS AS A LAKE RESTORATION TECHNIQUE,
Kent State Univ., OH. Dept. of Biological Sciences.
G. D. Cooke.
Water resources Bulletin, Vol 16, No 5, p 921-926, October, 1980. 3 Tab, 28 Ref.

Descriptors: *Eutrophication, *Water pollution prevention, *Lakes, *Linings, Nutrients, *Sediment covers, *Sediments, Bottom sediments, Water resources development, Recreation facilities, Plastics, Macrophytes, Nutrients.

Sediment covering has been suggested for controlling macrophytes and sediment nutrient release in order to effect lake restoration. The application of fly ash to control sediment phosphorus release apparently introduces more problems than it solves and should not be used. The possible adverse effects of fly ash application include high pH, dissolved oxygen depletion, biological reduction of sulfate to sulfide, heavy metal accumulation and toxicity, and physical clogging and crushing of organisms. Plastic sheeting has been suggested as a potentially effective technique to control macrophytes and nutrient release. Sand covered sheeting may also be useful in construction of swimming beaches. The largest scale reported experience with sheeting was the Marion Millpond, Wisconsin, where a black polyethylene sheet was used over ten hectares to control or retard macrophyte regrowth. In March of 1978 a finely porous compound, spun bonded DuPont Typar 3201 and 3202 black polypropylene, was applied to exposed sediments of Country Lake in Ohio. Further evaluation of this project is needed. Polyvinyl chloride has also been used. The use of plastic sheeting for control of macrophytes and sediment nutrient release has received insufficient evaluation to make conclusions about effectiveness, duration, application, and cost problems. Very little published information exists about the use of clays or sand to retard nutrient release or macrophyte growth. Heavier materials such as sand are apparently ineffective, as they sink into flocculent sediments. (Baker-FRC)

Descriptors: *Computer models, *Coal mines, *Strip mines, *Dissolved solids, Leaching, Salinity, Irrigation effects, Streamflow, Irrigation water, Selective withdrawal, Return flow, Reservoirs, *Montana, Tongue River, *Water quality control.

A computer model has been developed for spatial and temporal simulation of streamflow and dissolved solids in the Tongue River from the Tongue River Dam to Miles City, Montana. User-defined plans of surface coal mining and agricultural development permit evaluation of potential changes in dissolved solids resulting from leaching of overburden material used to backfill mine pits and from withdrawal and return flow of irrigation water. Provision is made for simulation runs using increased streamflow from a proposed larger reservoir intended to replace the present Tongue River Reservoir. Simulations at mean streamflow indicated that mining 119,600 acres of federally leased coal tracts may increase by 4.8 percent the present annual dissolved-solids concentration in the Tongue River at Miles City. Simulations using the proposed Tongue River reservoir show substantial reductions in dissolved-solids concentration when paired with similar simulations using the present Tongue River Reservoir. When compared on a per-acre basis for the study area, the dewatering caused by irrigation increases dissolved-solids concentration more than the input of leachates from surface coal-mining operations. Water Science and Technology, Vol 13, No 11/12, p 645-650, 1981. 4 Fig.

Descriptors: *Telemetry, *Water management, Oxygen, *Aeration, Remote sensing, Computers, Automation, *Water pollution control, Rivers, *Mosel River, Weirs, Spillways, Water pollution sources, Wastewater, Navigation, Plankton, *Germany.

A temporary but substantial deterioration of the oxygen balance has been noted in the Mosel River due to weir steps which were constructed to aid in the use of the river for navigational and hydroelectric purposes. The river is loaded by sewage effluent and self polluted by plankton. Overspill has been provided at the barrages to alow artificial aeration to be carried out, thus increasing the oxygen content of the river water. The overspilling is to the debit of hydropower and should thus be as small as possible but sufficient for river protection. An accurate adaptation to the aeration demand has to be figured temporally and locally. Such aeration is needed mainly during the nighttime hours. In individual impounding sections very different oxygen contents can occur at the same time. Therefore it is necessary to gain information at several points. The staff at the hydropower stations needs information on the amount of aeration water, on the weirs and the hours of overspill 12 to 24 hr in advance. The data is gained through a telemetric system. Automatic data transmission was begun in August 1978. The system works nearly without loss of data. The transmission has been interrupted several times by lightning. (Baker-FRC)

PERFORMANCE TESTING OF THE SOVIET OIL/DEBRIS SKIMMER,
Mason and Hanger-Silas Mason Co., Inc., Leonardo, NJ.
H. W. Lichte.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-244790, Price codes: A03 in paper copy, A01 in microfiche. Environmental Protection Agency EPA-600/S2-81-154, September, 1981. 4 p, 2 Fig. 68-03-2642.

Descriptors: *Oil skimmers, *Oil spills, *Cleanup operations, Oil recovery, Oil pollution, Viscosity, Harbors, Water pollution control, *USSR.

The oil skimming capability of a specially modified Soviet oil/debris skimmer was investigated at the Oil and Hazardous Materials Simulated Environmental Test Tank (OHMSETT) in 1979. The self-propelled vessel is 17.7 m long and weighs 39 metric tons. The 111-kw diesel engine drives a ducted propeller, water jet propulsion system. The vessel is capable of 5 knots forward speed and skims effectively at speeds of 0 to 1.0 m/s. The unique combination of various weir designs into one system, vessel mobility, the efficient use of energy, a series-type of oil/water gravity separator, and the propulsion techniques all suggest that this model is an effective harbor skimmer. The oil recover rate of 12.4 cu m/hr was confirmed using high-viscosity test oil in calm water conditions. Recovery efficiency was 85% at 0.77 m/s forward speed, and throughout efficiency was 90% at 0.51 m/s forward speed. Performance dropped when low-viscosity oils were skimmed at faster speeds and higher wave conditions. The skimmer collected 64% of the 81.3 cu m oil volume encountered during the test program. EXPERIENCES WITH FLOATING RESERVOIR COVERS AT THE MANCHESTER WATER WORKS,
Manchester Water Works, NH.
D. Kittredge.
Journal of the New England Water Works Association, Vol 95, No 4, p 258-263, December, 1981. 1 Tab.

Descriptors: *Reservoirs, *Water pollution sources, Reservoir operation, Surface water, Drinking water, Water quality, *Manchester, New Hampshire.

Pollution of open reservoirs by airborne matter, birds and animals and often by man himself has been a problem at the Manchester Water Works for a number of years. A decision was reached in 1969 to install a system of synthetic rubber floating covers over the three open reservoirs as the first phase of a general improvement plan to upgrade and protect water quality. The second phase of the plan involved construction of a complete and modern water filtration system. The Manchester Water System consists of more than 355 miles of mains ranging in diameter from 2 to 36 inches and three principal water distribution reservoirs with a combined storage capacity of 41 MG. The first winter of floating cover operation was a severe test, with a prolonged cold spell of sub-zero weather lasting most of the month of February, resulting in a massive ice buildup along reservoir walls. Several large tears were noted in the cover membrane the following spring. Extensive ice and vandalism caused one of the covers to be removed in 1979. The condition of the remaining two covers is questionable, but the utility estimates a total life expectancy of 10-12 years. During the first year of floating cover operation, bacterial quality of treated water improved substantially, chlorination dosages were lowered, and as a result chemical costs were reduced by about 44%. J. Murphy.
Journal of the New England Water Works Association, Vol 95, No 4, p 248-252, December, 1981.

Descriptors: *Reservoirs, Water supply development, Water quality, Water pollution sources, *Water pollution control, *Water supply systems, *Reservoir covers, *New England, Design criteria.

Some of the concepts and problems which must be considered during the design of various covering systems for reservoirs are discussed. One of the earliest steps in the process is to evaluate the problems that the cover is supposed to correct. These may include airborne contaminants, surface runoff, ground-water, vandalism, birds, animals, and aquatic organisms. Open reservoirs which can be evaluated in terms of cost effectiveness of covering are usually among the following: steel reservoirs, concrete reservoirs, and earthen reservoirs. An evaluation of the type of roof system to employ for an open water distribution reservoir must consider such factors as foundation soils, access to the area, location of the facility both from the standpoint of vandalism and topography, climate of the area, dead and live load requirements, the life of various construction materials, the aesthetics of the completed facility, the down-time required for construction, and finally, the relative costs of the various systems. THE ROOFLOAT (FLOATING) COVER SYSTEM FOR LIQUID STORAGE,
Globe Linings Inc., Long Beach, CA.
W. B. Kays.
Journal of the New England Water Works Association, Vol 95, No 4, p 253-257, December, 1981.

Descriptors: *Reservoirs, Water supply development, Water quality, Water pollution sources, Water resources development, Water storage, *Water pollution control, Reservoir covers, *Design criteria, Economic aspects, Water supply.

An attempt was made to develop alternatives to the conventional roof structure for reservoirs. In examining the possibilities of an inflated membrane, the largest drawback appeared to be the high-rise feature. Reservoir owners demanded a flat or nearly-flat profile to ease public relations problems. A compromise was worked out to a 10% rie which owners had to accept if they wished to benefit from the lower costs and other advantages associated with the inflatable roof. The coated fabric that gave the best combination of availability, low cost and high strength was the popular 22/24 oz per sq yd construction, using a 5.5 oz nylon with a 60:40 unbalanced white PVC coating. Disadvantages of this material outweighed the advantages, and a new flexible floating cover system, ROOFLOAT, was designed. The ROOFLOAT cover is essentially a stress-free system. As further developments are made, the following qualifications for a cover should be met: a high degree of outdoor weatherability, with a 50 yr minimum life expectancy in all climates; a relatively simple and effective field and factory seaming procedure that will yield joints that cannot fail; possible field installation at all temperatures above freezing; no delamination of reinforcement fibers or membrane plies; easy repair of the membrane at any age; and physical properties which would allow the aforementioned conditions to be met. The concept of the state of a system was used to link together state space modeling, dynamic programming, and Markov chain analysis for optimization of reservoir systems in monthly stages over a year. The mathematical description of the inflows to the reservoir system and the response of the system to inflow and releases were formulated as the state space model. This was incorporated within an explicit dynamic programming procedure as the state transition equation. Transition probabilities of the state variables were found for each decision and tested in dynamic programming. Those for the optimal decisions were used in a Markov chain analysis to determine the statistical characteristics of the state and decision variables if the reservoir is operated for a long period with the optimized policy. This method was used to determine the operating policies for the proposed Wastasheamu Dam, Nevada, designed for irrigation water supply, hydroelectric power, and flood control. Operating policies developed by two techniques, independently distributed or serially correlated monthly flows, were similar over the midrange of flows but different for very high and low inflows. chance constraints were used to avoid the probability that storage would be outside the desired range. These constraints may be varied to obtain tradeoffs between economic efficiency benefits and the risk of violating storage limits. (Cassar-FRC)

Energy, Vol 6, No 4, p 323-331, 1981. 3 Fig, 8 Ref.

Descriptors: *Hydroelectric power, *Model studies, *Drought, Long-term planning, Planning, Energy, Electric power production, Linear programming, *Capital costs, Operating costs, Costs, Fuel, *New Zealand.

A linear programming model for long-range planning of electricity generation in areas with a high proportion of hydro power is presented. It considers the effects of both low and high water inflows. Increases in model size are kept to a minimum. This is important in large time-staged models and in multi-fuel supply models. The least cost choice for reserve capacity must account for capital costs of the generating capacity, but also the fuel and operating costs incurred when water intake is low. The model described herein has been implemented in a multi-fuel model of the New Zealand energy system. (Cassar-FRC)

Water Resources Research, Vol 17, No 5, p 1349-1359, October, 1981. 4 Fig, 5 Tab, 11 Ref. OWRT A083-KY.

Descriptors: Planning, *Water resources development, Resources development, *Multiobjective planning, Water supply development, Model studies, Computers, Flow, *Network design.

A multiobjective branch and bound method is proposed for analyzing problems involving a network flow structure which are commonly found in the water resources planning field. The method appears to be computationally efficient due to the special problem structure associated with the nonlinear network flow formulation. The method was successfully applied to a realistic regional wastewater planning problem of a moderate size. Also proposed is a multiobjective imputed value analysis which makes use of the branch and bound tree structure and allows comparison of the importance of facilities in the network as represented by individual arcs or sets of arcs. The mathematical formulation and the analysis procedure of the method are described, and the potential usefulness is demonstrated. A Fortran program for implementing the algorithm is available and was used to analyze the example problem consisting of about 650 executable statements. It is an interactive program which provides information on the growth of multiobjective branch and bound trees and the generation of noninferior alternatives in the process of computation. WATER REUSE PLANNING MODELS: EXTENSIONS AND APPLICATIONS,
Texas Univ. at Austin. Dept. of Civil Engineering.
G. Ocanas, and L. W. Mays.
Water Resources Research, Vol 17 No 5, p 1311-1327, October, 1981. 7 fig, 8 Tab, 14 Ref. OWRT 14-34-0001-9483.

Descriptors: *Model studies, *Water reuse, Decision making, Planning, Wastewater treatment, Water treatment facilities, Sinks.

This paper presents a real world application of both the single period and the multiperiod planning models to a region that includes the City of San Antonio, Texas. The use of the single period model is shown through a set of different planning scenarios for the years 1980, 2000, and 2030. The multiperiod model was applied to a planning horizon consisting of three planning periods beginning in the years 1980, 2000, and 2030. The optimal capacity expansion of treatment facilities was determined, considering the capacities already available at the beginning of the planning horizon. The system consists of many elements: water sources, water treatment plants, wastewater treatment plants, and water sinks. The following conclusions were drawn from the study. Optimal water allocation planning should incorporate both water and wastewater systems conjunctively to better assess the impact of water reuse. Economies of scale have a significant effect on the cost and consequently the configuration of the water systems. The solution of a sequence of independent single period problems does not provide an accurate representation of the growing nature of the system. Therefore single-period planning is best suited to assess the impacts of different planning scenarios under current conditions. The performance of the solution algorithm was apparently influenced by the selection of the initial point. The final solution can be dependent upon the specified initial solution, indicating the importance of selecting a good initial point. The model, however, does not provide the ultimate answer to the problem of water allocation and capacity expansion within a region. The model is deterministic; no stochastic or seasonal variations are included. Finally, the model does not guarantee global optimality due to the nonconvex structure of the constraint set and the concavity of the objective function when economies of scale are incorporated. (Baker-FRC)

TRANSGLOBAL VARIATIONS IN THE PLANNING OBJECTIVES AND CRITIQUES,
Ministry of Water and Power, Islamabad (Pakistan).
S. M. H. Bokhari.
Water Supply and Management, Vol 5, No 6, p 377-389, 1981. 22 Ref.

Descriptors: *Water management, *Water policy, *Planning, *Pakistan, Agriculture, Water resources development, Indus Basin, Environmental quality, Economic development, Social aspects, Political aspects, Technology, Water law, Comparison studies, United States.

The history and present state of planning and management of water resources is contrasted for Pakistan and the U.S., two countries with greatly differing economic and social conditions. In the early U.S. planning was almost nonexistent on a federal scale. Water resources were regarded as exploitable for economic development. The battle between conservationists and developers began early in the 20th century and reached a climax during the 1960's. During the 1930's regional and multi-purpose development projects were popular. In 1973 the Water Resource Council adopted two planning objectives, national economic development and environmental quality. Pakistan's history of water resources planning objectives includes the British colonial period 1856-1947, during which the few water projects were greatly underdesigned, wasteful, nonscientific, and without regard to future problems such as waterlogging and salinity of the soil. Investments were minimized. A Development Board was created a year after Independence to prepare a 5-year plan. These plans have been prepared regularly since 1955. Objectives for water resources development included conservation, development of new surface and groundwater resources, increasing irrigated areas, reclamation of waterlogged and saline soils, flood and erosion control, and a research program. Project evaluation in Pakistan is based on benefit-cost analysis. The many differences in background and policy between the two countries make it impossible to effectively apply planning objectives from the U.S. in the developing countries. (Cassar-FRC)

SIMULATED INTERACTIONS BETWEEN THE PROPOSED NARROWS RESERVOIR AND THE WATER-TABLE AQUIFER ALONG THE SOUTH PLATTE RIVER, MORGAN COUNTY, COLORADO,
Geological Survey, Lakewood, CO. Water Resources Div.
A. W. Burns.
Geological Survey Water-Resources Investigations 80-119, 1981. 61 p, 24 Fig, 11 Tab, 9 Ref.

Descriptors: *Model studies, *Preimpoundment, *Water table, *Surface-groundwater relations, Simulation analysis, Forecasting, Reservoirs, Dams, *Colorado, Morgan County, Narrows Reservoir, *South Platte River, Groundwater movement.

A computer model, including a ground-water-flow component and a mass balance reservoir-operations component, was developed to simulate the proposed Narrows Reservoir and the adjacent alluvial aquifer of the South Platte River, Morgan County, Colo. This model, using a weekly time step, simulated the transient interactions of these two systems for an initial-fill condition and general-operational condition. A sensitivity analysis was made to test the effects of possible errors in the description of aquifer characteristics on the model results. The initial-fill simulation indicated that to fill the reservoir when hydraulic connection between the surface-water system and the aquifer is simulated would take 2 additional years than if no connection was assumed. Simulated ground-water return flow to the river downstream of the proposed dam was about 85 percent of the estimated maximum values, computed under steady-state conditions in an earlier study. The general operation simulation indicated that during the period of lowest reservoir contents the aquifer provided about 80,000 acre-feet of recoverable storage to the reservoir's capacity. Average return flow was only about 70 percent of the estimated maximum values computed in the earlier, steady-state analysis. Monthly ground-water outflow from the reservoir to the aquifer ranged from 55,200 to -10,400 acre-feet. Parameters tested for sensitivity, in order of decreasing sensitivity, were: Hydraulic conductivity, specific yield, hydraulic connection between

reservoir and aquifer, local recharge, boundary conditions, and dam permeability. The probable error in the parameters tested would not seem to warrant significant new data collection. (USGS)

DETERMINATION OF EFFECTIVE WELL BLOCK RADII FOR NUMERICAL RESERVOIR SIMULATIONS,
Systems, Science and Software, LaJolla, CA.
J. W. Pritchett, and S. K. Garg.
Water Resources Research, Vol 16, No 4, p 665-674, August, 1980. 7 Fig, 6 Tab, 6 Ref.

Descriptors: *Wells, *Reservoirs, *Simulation, *Numerical analysis, Mathematical equations, Model studies, Underground reservoirs, *Groundwater movement.

When using a numerical simulator to model underground reservoir behavior, it is often necessary to use well blocks, which are grid blocks containing a well, with dimensions much larger than the well diameter. Practical procedures have been developed for making reasonable estimates of well bore sandface conditions from the well block conditions calculated by numerical reservoir simulations. Assuming that pressures will equilibrate much more rapidly on a subgrid scale than in the reservoir as a whole, the subgrid flow may be treated as steady flow. The conditions at the sandface may then be deduced from mean well block conditions by assuming that the latter obtain at a definite distance, defined as the 'effective well block radius', from the well. However, the value of this effective well block radius must be established in terms of the size of the well block and other relevant parameters. Examination of the grid pressures obtained in the numerical solution of liquid flow into a single well located in both radial and rectangular grid blocks showed that the effective well block radius depends on the shape of the grid block (radial or rectangular), the type of mesh (uniform or otherwise), and the character of the spatial discretization scheme, among others. INPUT-OUTPUT AND BENEFIT-COST ANALYSIS FOR WATER RESOURCE DEVELOPMENT PROJECTS,
Science and Education Administration, Lincoln, NE.
R. T. Clark.
Water Resources Bulletin, Vol 16, No 1, p 36-40, February, 1980. 9 Ref.

Descriptors: *Water resources development, *Cost-benefit analysis, Regional development, Resources development, Urban planning, Planning, *Input-output analysis.

The purpose of this research was to aid the use of input-output (I-O) in conjunction with benefit-cost (B-C) analysis for water resource development type projects. Terminological differences and differences due to benefit measuring methods are discussed. Proper use of the I-O model for estimating the secondary methods are discussed. Proper use of the I-O model for estimating the secondary effects depends in part on how the project benefits were valued, whether project outputs were sold to final or intermediate demand, and whether project output is represented by an endogenous sector. The analyst must look to the total effects on household income to determine secondary effects for B-C. Consequently, I-O models closed to households are more helpful than those that are open. Access to only final demand multipliers will limit the usefulness of I-O for estimating secondary benefits and costs, since final demand multipliers measure gross output changes instead of household income changes. Even income multipliers are not as helpful as the entire I-O model. There are many issues related to proper use of the I-O model that depend on the analyst's knowledge of I-O techniques and knowledge of how a specific model was developed. A result is that even though I-O can be helpful it can also be rather easily misused and can, therefore, provide misleading information. (Baker-FRC)

DEMAND SIGNALS FOR URBAN DRAINAGE AND FLOOD CONTROL PROJECTS,
North Carolina Water Resources Research Inst., Raleigh.
N. S. Grigg, and H. A. Vance.
Water Resources Bulletin, Vol 16, No 1, p 69-71, February, 1980. 1 Fig, 1 Tab, 5 Ref.

Descriptors: *Urban drainage, *Planning, *Economic aspects, *Flood control, Public opinion.

A new method is presented for determining the demand for urban drainage and flood control projects and to show how it can be used as part of an integrated planning procedure for setting priorities and allocating funds to competing projects. The method was devised by the Los Angeles County Flood Control District. The basic objective of the plan is to develop a logical rational planning procedure that will consider public demand for projects and allow planning to take place in the open. This ensures that opposition will be identified and dealt with early in the planning process and that surprises will be minimized. Results should yield a better utilization of the public funds both for planning and for implementation. The BENEVAL equation as developed represents a major step, as it is a surrogate measure of the public perception of the value of projects. It allows both screening for projects whose further development should be considered based on economic justification and prioritizing to allow greatest attention to those projects which are most urgent. 6B. Evaluation Process

AUBURN DAM: A CASE STUDY OF WATER POLICY AND ECONOMICS,
Montana Univ., Missoula. Dept. of Economics.
J. W. Duffield.
Water Resources Bulletin, Vol 16, No 2, p 226-234, April, 1980. 4 Tab, 39 Ref.

Descriptors: *Cost-benefit analysis, *Water policy, *Economic analysis, Benefits, *Dams, *Auburn Dam, American River, *Sacramento, California, Water resources development, Earthquakes, Recreation, Irrigation, Dam failure.

This paper critically analyzes the economic justification of the Auburn Dam, part of the $1.5 billion Auburn-Folsom south unit of the Bureau of Reclamation's Central Valley Project in California. Construction on this dam has been stopped because the high thin arch structure, located on a major geological fault, is being recesigned for greater earthquake resistance. Errors in previous benefit-cost estimates were large. Irrigation benefits were overestimated and recreational losses underestimated. Revised benefit-cost ratios are 0.61 at 3 and 1/8% discount rate and 0.18 at 6 and 5/8% discount rate. Original estimates were 1.72 and 0.79 at the respective discount rates and failed to consider the cost of the permanent inundation of 48 miles of the American River Canyon or a probability-weighted estimate of catastrophic earthquake loss (much of metropolitan Sacramento would be inundated). This paper recommends that the project should not be continued. Suggestions for improving benefit estimation are: (1) use several approaches, (2) give priority to direct evidence of willingness to pay, as in market prices, (3) perform a site-specific analysis if results are sensitive to changes in average national numbers parameters, and (4) do not ignore destruction of natural environments such as wild rivers. (Cassar-FRC)

EVALUATING DIRECT BENEFIT ESTIMATION PROCEDURES FOR IRRIGATION PROJECTS: A SIMPLIFIED APPROACH,
Arizona Univ., Tucson. Dept. of Agricultural Economics.
D. C. Cory, and J. Daubert.
Water Resources Bulletin, Vol 17, No 6, p 1066-1070, December, 1981. 1 Fig, 1 Tab, 11 Ref.

Descriptors: *Benefits, *Cost-benefit analysis, *Irrigation programs, Agriculture, Corn, *Nebraska, Economic analysis, Error analysis, Irrigation efficiency.

Commonly used methods for estimating direct benefits from irrigation are compared with a new method which estimates the sum of the changes in producers' and consumers' surplus. Errors inherent in the traditional methods are computed. Traditional methods measure impacts on the commodity markets by assuming the supply is inelastic. They either assume no change in commodity prices and calculate net returns to project farmers or allow commodity prices to fall in accordance with a given elasticity of demand and subtract commodity production costs from the associated area under the commodity demand curve. The new approach is used to evaluate 3 similar irrigation projects in Nebraska. Errors in benefits were 2% for the smallest project (10,000 acres of corn), and 8% and 15% for the larger projects (44,000 and 77,000 acres), respectively. (Cassar-FRC)

ENVIRONMENTAL THRESHOLD FUNCTIONS FOR USER ORIENTED RESOURCE PLANNING AND MANAGEMENT,
Illinois Univ. at Chicago Circle. School of Urban Sciences.
J. S. DeBettencourt, and G. L. Peterson.
Water Resources Bulletin, Vol 17, No 6, p 1050-1055, December, 1981. 2 Fig, 2 Tab, 10 Ref.

Descriptors: *Management planning, *Recreation, *Evaluation, Planning, Rivers, Surveys, Model studies, *Recreation facilities, *Site selection.

A method for assessing and measuring recreational site quality, called environmental threshold modeling, is described. It is based on the idea that persons using the recreation facilities have specific identifiable criteria which can be expressed as a mathematical function of site characteristics. The function separates acceptable recreational settings from unacceptable settings, hence the term, threshold function. The individual specific threshold functions can be combined to produce a population specific threshold function that gives the proportion of the population that finds a particular setting acceptable for a specific activity. Canoeists using the Pine River in Michigan's Manistee National Forest were asked to state whether or not each of 15 randomly generated combinations of characteristics would be acceptable for recreational canoeing. The characteristics were four levels each of water condition (pure to undesirable), degree of development (wilderness to urban), crowding/use (no other users to large number of users), trash/litter (none to heavy), and skill level required for canoeing (expert to beginner). The equation predicted that 80% of those surveyed would find characteristics of the Pine River site acceptable for use. If littering and crowding were reduced, the proportion of the population finding the conditions acceptable would rise to 93%. (Cassar-FRC)

FLOOD PROBABILITY ESTIMATION,
British Columbia Univ., Vancouver. Dept. of Civil Engineering.
S. O. Russel.
Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 108, No HY1, p 63-73, January, 1982. 2 Fig, 4 Tab, 12 Ref.

Descriptors: *Flood forecasting, *Design floods, *Estimating, Hydrologic data, Flood data, Flood frequency, Susquehanna River, Carpenter Creek, British Columbia, Streamflow, Flood peak, Numerical analysis, Computer programs.

A procedure is presented for estimating design floods from the many types of hydrologic information available, even though there is not sufficient data for conventional frequency analysis. A compound distribution is used, and parameters of the underlying distribution are updated using Bayes' theorem. This permits subjective information to be combined with recorded data. The subjective information, not generally usable for traditional frequency analysis, may include a few recorded

LIBRARY U. OF I. URBANA-CHAMPAIGN

floods, memory of bridges not being overtopped, evidence of a very large flood, envelope curves for the area, and river cross-sections. Numerical methods are used because analytical procedures are too limited. A computer program is used for calculations. Examples are given for a hypothetical case and for Carpenter Creek, British Columbia, and the Susquehanna River. The sparser and more uncertain the available data, the more conservative the results. REGULATING CORROSIVE WATER,
Environmental Protection Agency, Washington, DC.
R. Anderson, and D. Berry.
Water Resources Research, Vol 17, No 6, p 1571-1577, December, 1981. 5 Tab, 22 Ref.

Descriptors: *Cost-benefit analysis, *Corrosion control, *Public health, *Water treatment, Benefits, Drinking water, Regulations, Lead, Toxicity, Cadmium, Asbestos, Water softening, Diseases, Lime, Economic analysis.

The benefit-cost relationships of an EPA proposal to regulate the corrosvity of drinking water are examined. Corrosivity may result from low pH, low buffering capacity, presence of dissolved oxygen, high total dissolved solids, high halogen and sulfate/alkalinity ratio, and high temperature. The major health effects of corrosive water are lead toxicity, increased incidence of hypertension and cardiovascular disease produced by cadmium, and the possibility of cancer from ingestion of asbestos fibers. Possible benefits of reducing corrosivity are less health risk, fewer operations and maintenance problems, and improved esthetics (reduction of discolored water and stained fixtures). Negative effects of increasing the water hardness to reduce corrosivity are negligible. Evidence indicates that water treatment to reduce corrosivity is warranted, especially for larger systems. Costs per life saved vary from $1720 (145 lives saved per year) in a 100 mgd plant serving 1 million people to $114,000 (0.0036 lives saved per year) in a 2500 gpd plant serving 2500 people. Annual per capita costs for lime treatment of soft water range from 25 cents for the 100 mgd plant to $16.40 for the 2500 gpd plant. This study illustrates the uncertainties involved in placing an economic value on benefits from reduction in incidence of diseases. (Cassar-FRC)

Descriptors: *Hydroelectric power, Prediction, *Nigeria, *Developing countries, *Costs, Water demand, Water use, Interest rates, Project benefits, Energy conservation.

Nigeria has a hydropower potential of 9500 MW, including 1300 MW from 21 minor sites. Only 8% of this or 800 MW has been developed. Early development of hydropower will not only reduce the burden on Nigeria's crude oil supply, but will also have an impact on agriculture, fish industry, fresh water supply, navigation and employment. The rate of hydropower development is heavily dependent on international loans from industrialized nations. Total hydropower generating capacities in 1985 and 1995 are expected to be 3245 and 4895 MW, respectively, reaching 8185 MW by 2000. (Cassar-FRC)

REVERSING WATER POLLUTION STANDARDS IN AN UNCERTAIN WORLD,
Geological Survey, Reston, VA.
W. D. Watson, and R. G. Ridker.
Land Economics, Vol 57, No 4, p 485-506, November, 1981. 4 Fig, 6 Tab, 14 Ref.

Descriptors: *Decision making, *Water pollution control, *Water quality standards, Planning, Nonpoint pollution sources, Water pollution sources, Regulations, Legal aspects, *Cost-benefit analysis, Benefits.

The overall results of a decision analysis of EPA's water pollution control policies indicate that lower costs for implementing these controls would be incurred if significant amounts of additional information were gathered and decisions changed accordingly. Little concrete information is available concerning the contribution of nonpoint pollution sources to water quality degradation. There is a possibility that more pollution control at lesser cost could be attained by reducing nonpoint source pollution than by upgrading point source treatment systems. Two cases were assumed: (1) EPA is attempting to minimize expected costs and (2) EPA is establishing controls to achieve fishable and swimmable water quality. The expected cost savings provided by additional information are $400 million per year at present, rising to $2 billion per year in Case (1) and $1 billion per year in Case (2) by 2010. These estimates are considered conservative. (Cassar-FRC)

WHO WINS IN THE FIGHT FOR POLLUTION CONTROL,
J. Donnan.
Water and Pollution Control, Vol 119, No 11, p 9-10, 12, 1981.

Descriptors: *Benefits, *Environmental quality, *Industrial wastes, Economic aspects, *Water pollution control, Water pollution prevention, Cost-benefit analysis, Social aspects, Regulations, Environmental policy, Public health, *Canada, Waste treatment.

Pollution control efforts must be directed toward the opportunities and benefits that can be attained. Economic studies have indicated that pollution control expenditures by industry are small relative to other expenditure categories and investments. The adverse effects on inflation and economic growth are insignificant. It has been more effective to apply pollution control technologies and waste prevention early in an industrial process than to treat waste products at the end. The 3M company has saved $17.4 million in this way over 3 years. For example, in one installation ppainting equipment designed to avoid overspraying cost $45,000 and saved the plant $120,000 per year in resin and paint costs. Tightening flanges at a Union Carbide plant saved $2,000 per day in raw material costs. Other possibilities for combined pollution and cost reduction are avoiding spills, reclaiming materials (such as wood fibers in paper mills), running a clean and tidy operation, using low sulfur fuels, changing a process to a less polluting one (producing chlorine for pulp bleaching by a mercury free process), producing saleable products from waste materials (suluric acid from SO2), and early environmental assessments in the planning or new plant construction. The public benefits of pollution control include reductions in pollution damage and increased enjoyment of a cleaner environment. Pollution costs are borne by a small, easily identifiable segment of society; benefits are spread over a large, less easily identifiable group. (Cassar-FRC)

THE FINANCING OF PRIVATE SMALL SCALE HYDROELECTRIC PROJECTS.
Franklin Pierce Law Inst. Center, Concord, NH.
Available from the National Technical Information Service, Springfield, VA 22161 as DOE/CE/04934-44, Price codes: A06 in paper copy, A01 in microfiche. Department of Energy DOE/CE/04934-44, March, 1981. 106 p, 17 Tab, 1 Append. AS02-78RA04934.

Descriptors: *Hydroelectric plants, *Financing, *Economic feasibility, *Loans, Government finance, Costs, Marketing, Economic aspects, Regulations.

As a result of legislative and regulatory improvements, small scale hydroelectric (SSH) development is viewed as a potentially profitable enterprise. However, the lack of recent models for the development of SSH projects causes problems in the financing of these projects. A lack of developer information and a lack of lender information can combine to make it difficult to obtain funds necessary for the development of projects characterized by relatively large fixed costs, and whose only underlying security is the value of the power output. This manual is a description of the financing process associated with the private development of SSH projects, and is intended to provide the developer with some assistance in meeting the challenge of deciding how to proceed with the critical task of arranging the financing of his project. In any business venture, the business plan is a crucial guide for both internal and external financing decisions. The financing of SSH projects differs from most small business loans in that a SSH project usually requires an exceptionally large ratio of debt to equity, has an unusual marketing structure and is exposed to a pervasive regulatory scheme. A business plan should address the variables affecting the size, structure and cash flow and show how they would affect the project. The three business forms considered are corporations, Subchapter S corporations, and partnerships. Sources of funds which should be considered: commercial banks and savings and loan associations; manufacturers of hydroelectric equipment; investment bankers; state and municipal industrial development authorities; and federal financing assistance. Descriptors: *Energy, *Fuel, *Water resources development, *Prices, *Hydroelectric power, *Geothermal power, Economic aspects, Forecasting, Future planning, Economic aspects, Pumped storage, Resources development, River basin development, Technology.

Two estimates of future growth of emerging energy technology in the years 1985, 1990, and 2000 were developed to be used as a basis for conducting Water Resources Council assessments. The two scenarios are called the high world oil price (HWOP) and low world oil price (LWOP) cases. The scenarios were generally derived from assumptions of he Second National Energy Plan (NEP II), including estimates of high and low world oil price cases growth rate of GNP, and related economic parameters. The overall national energy growth inherent in these assumptions was expressed as a detailed projection of various energy fuel cycles through use of the Fossil-2 model and regionalized through use of the strategic Environmental Assessment System (SEAS). These scenarios are for the use of regional analysis in examining the availability of water for and the potential impacts of future growth of emerging energy technology in selected river basins. The energy scenarios provide projections for the following categories of emerging energy technology: coal gasification; coal liquefaction; oil shale; geothermal; enhanced oil recovery; solar and biomass; small scale, low head, and pumped storage hydroelectric; and advanced coal combustion. DETERMINING FEASIBILITY OF SMALL-SCALE HYDROPOWER,
Tudor Engineering Co., San Francisco, CA.
D. C. Willer.
Journal of the Energy Division, Proceedings of the American Society of Civil Engineers, Vol 107, No EY2, p 209-217, December, 1981. 4 Fig, 4 Tab, 3 Ref.

Descriptors: *Hydroelectric plants, *Cost-benefit analysis, *Feasibility studies, Hydraulic structures, Benefits, Dams, Powerplants, Energy, Economic analysis, Capital costs, Rate of return, Discount rates, Small-scale hydropower.

Techniques for evaluating the economic feasibility of small hydropower projects are presented and illustrated with examples. The simplest is the benefit-cost analysis, which compares annualized capital, operating, maintenance, and administration costs with the value of power produced. Another method is that using the internal rate of return, the discount rate where the benefit-cost ratio equals 1.0. It is computed by plotting several benefit-cost ratios vs. discount rates. A third technique is the discount cash flow analysis, which uses different escalation and discount rates to provide a variety of benefit-cost streams. The present worths of the benefit-cost streams are then assumed and a ratio computed. A further consideration is the primary energy factor, the energy required to manufacture and construct a hydro project. (Cassar-FRC)

WATER QUALITY ALLOCATED COST FOR MULTIPURPOSE RESERVOIRS,
New Mexico Univ., Albuquerque. Dept. of Civil Engineering.
R. J. Heggen.
Water Resources Bulletin, Vol 16, No 1, p 127-132, February, 1980. 7 Tab, 5 Ref.

Descriptors: *Water quality, *Cost allocation, Reservoirs, Cost sharing, Economic aspects, Cost analysis, Low flow, Water management, Wastewater treatment, Flow augmentation, *Multipurpose reservoirs, *Model studies, *Willamette River, Oregon.

Apportionment of reservoir costs may be appropriate to downstream waste water dischargers who by virtue of reservoir drawdown may be saved the expense of advanced secondary of tertiary waste treatment. Low flow augmentation from multipurpose reservoirs may yield significant water quality benefits. By using cost allocation, a portion of reservoir expense is assigned to water quality consumers, waste water dischargers who benefit from the increased receiving flow. Federal projects do not authorize such allocation. However, the procedure is increasingly appropriate for efficient multiobjective management. A model was constructed for waste water treatment costs, multipurpose reservoir costs, and water quality for Oregon's Willamette River. Water quality is expressed as a function of treatment and augmentation levels. Treatment cost needed to achieve a given quality of water without augmentation less treatment cost with augmentation gives an alternative cost of maintaining water quality. This alternative cost is used to determine water quality's share of reservoir cost via a cost allocation procedure. Water quality beneficiaries could be charged, under current conditions, about 7% of annualized reservoir expense. This charge is one-fourth of the expense of additional treatment facilities required if augmentation were not provided. (Baker-FRC)

MARGINAL COST AND SEASONAL PRICING OF WATER SERVICE,
West Virginia Univ., Morgantown. Regional Research Inst.
P. C. Mann, and D. L. Schlenger.
Journal of the American Water Works Association, Vol 74, No 1, p 6-11, January, 1981. 7 Ref.

Descriptors: *Water rates, *Marginal costs, *Seasonal variation, Pricing, Costs, Water demand.

Seasonal pricing is not synonymous with marginal cost pricing, although it is a logical consequence of the latter. Effective seasonal pricing requires that several criteria be fulfilled. There must be substantial variations in demand between peak and off-peak periods. Installed capacity requirement must be determined primarily by the peak demands of the specific system. The water utility must have peak demands which consistently occur during the same periods of the year, and the water utility must be able to estimate the difference in cost between meeting peak and off-peak demands. Several application problems can impede the use of seasonal pricing: cost calculation problems, prediction problems, excess revenue problems, income distribution and efficiency problems, needle peaking, shifting peaks, public acceptance, and metering difficulties. Systematic consideration of these problems is necessary for successful implementation of innovative pricing plans. They should not be regarded as barriers to reform in rate structures. (Carroll-FRC)

ON THE MARGINAL COST OF WASTEWATER SERVICES,
President's Council of Economic Advisers, Washington, DC.
S. H. Hanke, and R. W. Wentworth.
Land Economics, Vol 57, No 4, p 558-567, November, 1981. 3 Tab, 24 Ref.

Descriptors: *Wastewater treatment, *Pricing, *Marginal costs, Economic aspects, *Operating costs, Capital costs, Cost analysis, Economies of scale, Opportunity costs, Tariff.

The marginal cost of municipal wastewater services is analyzed for the purposes of designing a tariff for these services. In this paper marginal cost of wastwater services is defined so that the opportunity cost may be measured. The marginal cost is estimated for a hypothetical wastewater system, capacity 570,000 cu m per day, using the activated sludge process to serve a community of 300,000. In 1979 the total marginal cost for this system was 57 cents per cu m per year (54 cents major capital costs and 3 cents running costs). A two-part tariff is the most efficient and sound. Part 1 is the price per composite unit of use (57 cents in the above example) and part 2, the annual standing charge per customer (equal to the total cost of system overheads not directly related to use, but necessary to guarantee system maintenance over time). The overheads may include costs of meters, billing expenses, and connection costs. (Cassar-FRC)

Since two-thirds of the householders of Dar-esSalaam, Tanzania have low incomes and are unable to pay for high-priced sanitation systems, a new master-plan for low cost sewage disposal was drawn up from data on water consumption, plumbing facilities and income levels to accomodate the new housing developments with sanitary sewage disposal systems. The first stage of the plan, which will take from 1981-85 to complete, calls for the installation of improved pit latrines in most housing units, the implementation of a community health education program, and a rehabilitation and expansion of the pit emptying service. Funds for this stage will come from City Council, the World Bank, and other government aid agencies. Direct educational assistance will be given to households needing to install new latrines, while the cost of constructing and emptying the pit latrine will be borne directly by the owner of the house. The total cost for construction and maintenance of the pit latrine should account for no more than about 1.5% of total family income. The extension of the pit installation service should be funded out of general taxation because the annual user per capita costs are small and the direct beneficiaries of such a service are not identifiable. An Urban House Tax based upon the type of latrine present would be charged as a simple flat rate to each household. At present, pit emptying is carried out by the City Council and a number of independent operators who receive full payment when services are rendered or collect payments over the course of set periods by a more easily payable installment plan. FINANCING FEDERAL WATER DEVELOPMENT PROJECTS AND SHARING THE COSTS,
Water Resources Council, Washington, DC.
R. M. Wheeler, L. M. Eisel, and G. D. Seinwill.
Water Resources Bulletin, Vol 16, No 2, p 326-335, April, 1980. 5 Fig, 20 Ref.

Descriptors: *Financing, *Water supply development, *Cost sharing, Water management, Planning, Administration, Political aspects, *Federal jurisdiction, Economic aspects.

A brief survey is presented of past and present Federal involvement in water resources development, along with a closer look at the nature of cost sharing and an assessment of the varied assortment of existing Federal and non-Federal cost sharing provisions. Samplings of some relevant emerging issues are presented, with the focus on policy questions that are currently arising due to competing interests for water and water project funding. Several proposed strategies for dealing with cost sharing policy reform are discussed, with detailed emphasis on two current proposals under consideration. The joint venture approach results in an effective composite cost share which changes significantly but not drastically, from 19 to 35% non-Federal share for a hypothetical project. The block grant approach would alter the regional distribution of Federal water development funding from the South and West to the Northwest and North Central States. To be successful any strategy not only must be theoretically sound, but must be politically sound as well. Practical solutions must be sought through the existing political structure, as any realistic solution generally requires the transfer of a subsidy from one interest to another. (Baker-FRC)

THIRD-DEGREE PRICE DISCRIMINATION AND REGULATION IN THE MUNICIPAL WATER INDUSTRY,
Lafayette Coll., Easton, PA.
T. H. Bruggink.
Land Economics, Vol 58, No 1, p 86-95, February, 1982. 5 Tab, 17 Ref.

Descriptors: *Pricing, *Water rates, Regulations, Economic aspects, Water demand, Water supply, *Price discrimination.

This paper discusses the practice of third-degree price discrimination and the role of state regulation in governing rate structures as they concern the structuring of rates for municipally owned water utilities. The conclusions suggest that third-degree price discrimination is practiced by municipally owned water utilities. The average pice-marginal cost ratios for the residential, commercial, and industrial customer classes are 3.45, 2.32, and 1.52, respectively in the unregulated utilities, and 3.12, 1.81, and 1.04 in the regulated utilities. The differences are excessively large, with the industrial customers clearly identified as the benefited group. There is no evidence of internal subsidization across the customer classes. However, the excessive price discrimination is undesirable under the criteria suggested by Hollas and Friedland. Also noted are sharp reductions in the price-cost ratios for all customer classes in utilities regulated at the state level. The reductions are uneven, however, with the industrial and commercial customer classes receiving larger absolute and percentage reductions than the residential class. In regulated, municipally owned electric utilities the industrial customers had the lowest price-cost ratios. (Baker-FRC)

6D. Water Demand

DETERMINISTIC MODELS FOR PREDICTING RESIDENTIAL WATER CONSUMPTION,
Department of Transport and Works, Darwin (Australia).
N. A. Power, R. E. Volker, and K. P. Stark.
Water Resources Bulletin, Vol 17, No 6, p 1042-1049, December, 1981. 5 Fig, 4 Tab, 8 Ref.

Descriptors: *Water consumption, *Lawns, *Domestic water, *Model studies, Water demand, *Residential water, *Water use, Irrigation, Townsville, Australia.

Two deterministic models for forecasting residential water demand are presented. Lawn water requirements and in-house use are considered separately, then combined for a total predicted consumption. The in-house model requires the residence population, appliance ownership per residence, and water consumption of an appliance per use. It can simulate effects of changes in appliance ownership patterns, population distribution, appliance unit water use, and frequency of use. The lawn water model is a daily water balance model with a single soil moisture store. It operates in two phases, a drying phase through evaporation and transpiration and a wetting phase through rainfall and irrigation. Residential water consumption in Townsville, Australia, was modeled after a survey of a random sample of residences. In-house model results were 197 liters per capita per day; 205 liters per capita per day was obtained by measuring sewage flows. Simulations showed that increases of 100% in dishwasher ownership and garbage disposal ownership would increase average in-house consumption by 5.2% and 3.4%, respectively. Lawn water consumption was measured at five metered homes for 12 months. Simulated and actual water applied agreed within about 6 mm in the range of 669-885 mm seasonal irrigation water depths. AN ECONOMIST'S VIEW OF DEMAND PROJECTIONS CONSIDERING CONSERVATION,
California Univ., Santa Barbara. Dept. of Economics.
W. D. Morgan.
Water Resources Bulletin, Vol 16, No 5, p 941-943, October, 1980. 2 Fig, 6 Ref.

Descriptors: *Water demand, *Water conservation, *Water use, *Economic aspects, Prices, Water management, Water supply, Mathematical studies, Elasticity of demand.

An approach was developed to clarify and elaborate on procedures for measuring water use undder alternative conservation specifications. An attempt was made to place the analyses in terms of traditional economic analysis. Using this analysis, the effects of conservation can be divided into two classes, pure conservation effects and pure demand management. The use of demand management to reduce quantity demanded operates through an increase in the price of water, which means individuals move up their demand curve and choose a smaller quantity. Conservation policies incorporate other factors that affect water usage, while holding the price constant. An increase in the conservation percentage reduces the quantity of water demanded. Providing information on techniques or technology is very important to enable users to choose the proper amount of water needed to meet their specified goals. Some instruments to meet these goals are under the control of the water agency, while others are not. However, the variable price is always under the control of the water purveyors. (Baker-FRC)

GROUND-WATER CONDITIONS IN THE UPPER VIRGIN RIVER AND KANAB CREEK BASINS AREA, UTAH, WITH EMPHASIS ON THE NAVAJO SANDSTONE,
Geological Survey, Salt Lake City, UT. Water Resources Div.
R. M. Cordova.
Available from Utah Dept. of Natural Res. Div. of Water Rights 231 East 400 South Salt Lake City, Utah 84111. Utah Department of Natural Resources Technical Publication No 70, 1981. 87 p, 18 Fig, 3 Plates, 23 Tab, 30 Ref.

Descriptors: *Groundwater, *Aquifer characteristics, *Water quality, *Well yield, Well data, Pumping, Drawdown, Groundwater recharge, Water level fluctuations, Surface-groundwater relations, Groundwater availability, Water supply, Water demand, Chemical analysis, Maps, *Utah, Virgin River basin, Kanab River basin, Navajo Sandstone.

The upper Virgin River and Kanab Creek basins area in south-central Utah includes about 1,300 square miles in the upper Virgin River basin and about 650 square miles in the upper Kanab Creek basin. The sparsely populated area contains large coal reserves. Water occurs in both the unconsolidated and consolidated rocks. Principal aquifers in the unconsolidated rocks include older stream-channel deposits, lower parts of alluvial fans, and stream-valley alluvium. The most important consolidated-rock aquifer is the Navajo Sandstone of Triassic and Jurassic age. Other consolidated-rock aquifers of note include the Shinarump Member of the Chinle Formation of Triassic age, sandstone strata of Cretaceous age, and the Wasatch Formation of Tertiary age. Groundwater recharge is derived chiefly from precipitation on the area and is estimated to average about 80,000 acre-feet per year. Discharge occurs chiefly as seepage to lower stream reaches and evapotranspiration; natural discharge is estimated to total at least 62,700 acre-feet per year. In addition, about 5,000 acre-feet per year discharges as underflow into Arizona; and in 1977, at least 3,300 acre-feet was withdrawn by wells. Chemical quality of ground water varies considerably with geologic source. Water in the Navajo Sandstone and Wasatch Formation is generally fresh, containing less than 500 mg/L of dissolved solids in most places. Water in the Chinle and Moenkopi Formations of Triassic age and the Carmel Formation of Jurassic age is generally saline, containing 1,000 to 3,000 mg/L of dissolved solids in most places. (USGS)

CLEAN WATER FOR THE THIRD WORLD,
Biswas and Associates, Oxford (England).
A. K. Biswas.
Water Supply and Management, Vol 5, No 6, p 401-415, 1981. 12 Ref.

Descriptors: *Drinking water, *Public health, *Developing countries, United Nations, *Costs, International Drinking Water Supply and Sanitation Decade, Water resources development, Sanitation, World Health Organization, Education, Water supply, Water quality standards, Investment, Institutional constraints, Political constraints, Reviews.

Current information on the availability and use of potable water in developing countries is critically

reviewed. Weaknesses in the World Health surveys of 1962, 1970, and 1975 are incomplete information (China and several other countries were not included), countries overestimating or underestimating the status of clean water supplies either to improve their images or to call attention to their difficulties, the intermittent nature of water service in may locations, and differences in enumeration method among countries. Provision of clean water without concurrent improvements in sanitation and health education is very ineffective. Western world water quality standards cannot be imposed on developing countries because significant percentages of existing water suplies would be automatically condemned and cost of equipment and personnel to maintain these high standards would be impractically high. The goal should be a variable standard to suit the locale, people, infection risks, and finances. Many cost estimates for the Decade have been calculated and revised. The currently accepted cost is $300 billion, considered by many to be a serious underestimate. There is small chance that the Decade will meet its goals. Constraints that must be overcome to ensure success are the lack of funds in the developing countries, the priorities of the individual countries, the lack of institutional infrastructure in many areas, lack of trained manpower, and lack of understanding of local conditions. THE RELATIONSHIP OF ACCESSIBLE SAFE WATER AND ADEQUATE SANITATION TO MATERNAL AND CHILD HEALTH--LOOKING FORWARD TO THE DRINKING WATER AND SANITATION DECADE,
Water and Sanitation for Health Project, Washington, DC.
R. B. Isely.
Water Supply and Management, Vol 5, No 6, p 417-424, 1981. 3 Fig, 1 Tab, 14 Ref.

Descriptors: *Drinking water, *Public health, *Social aspects, Sanitation, International Drinking Water and Sanitation Decade, Benefits, *Developing countries, United Nations, Diseases, Women, Children.

The chief beneficiaries of planned improvements in developing countries' water supplies and sanitation will be women and children. The average East African woman uses 9% of her daily caloric intake to obtain water for the household, up to 27% in hilly country. Diarrhea and its effects account for 30% of deaths in Third World children 0 to 4 years old. Waterborne diseases are responsible for undernutrition and many other ailments. Benefits from safe water supplies and improved sanitation are three fold: a better quality of life for women, reduced mortality and morbidity in young children, and the advantages that mother and child experience as a single bio-social unit (increased birthweight of infants, prolonged breastfeeding period, more time for child care, and a reduction in birth rate). WATER RESOURCES APPRAISAL FOR HYDROELECTRIC LICENSING: SEVIER LAKE BASIN, UTAH.
Federal Energy Regulatory Commission, San Francisco, CA. San Francisco Regional Office.
Appraisal Report, September, 1980. 61 p, 20 Fig, 10 Tab.

Descriptors: *Hydroelectric plants, *Water resources development, *Water demand, *River basin development, Irrigation, Flood control, Precipitation, Runoff, *Sevier Lake basin, *Utah.

The Sevier Lake basin is a major land-locked drainage basin covering all or portions of 11 counties in southwest Utah and a small portion of one county in Nevada. Average annual precipitation ranges from about 8 inches in the western desert to over 30 inches in the mountains. In spite of groundwater tables, which tend to recharge the Sevier River, losses to evapotranspiration aided by irrigation deplete flows in the river to the extent that runoff reaches Sevier Lake only during rare high flows. Approximately 400,000 acres (less than 5% of the total basin area) are irrigated. Fourteen small operating hydroelectric powerplants in the basin have a combined installed capacity of 6,260 kw, of which 77% is under license. The basin's hydroelectric plants produce about 34 gigawatthours annually which is about 5% of the forecasted 1978 energy requirement. There are two flood control projects in the basin. About 38% of the basin's installed hydroelectric capacity is developed in the 2,400 kw Upper Beaver plant. The Upper Beaver plant is in good condition and capable of being operated efficiently for a number of years in the future. It is not considered to be economically justified for the company to make repairs for resumed power production at the Lower Beaver plant. Water resource projects which have been considered for development include: a land rehabilitation program; a water diversion project; two pumped storage projects, and two low-head hydroelectric powerplants. THE WELSH APPROACH TO WATER RECREATION,
S. Le Lievre.
Water, No 42, p 29-31, 1982. 3 Fig.

Descriptors: *Water use, *Recreation, *Water demand, Boating, Fishing, Lakes, Reservoirs, *Wales, Regulations.

The Welsh Water Authority Strategic Plan for Waterspace Recreation and Amenity was recently released. Representative bodies of users and individuals with interests in countryside conservation and wildlife protection have given unequivocal approval and support to the authority's proposals, which took six years to complete. Uppermost in the minds of the authority is the conservation of the countryside in which the visible assets of water space are located. Much of the time taken in preparing the master plan was occupied in consultations with all types of users, in order to search for practical solutions to possible areas of conflict or clashes of interest. THE SEVEN-TRENT STUDIES OF INDUSTRIAL WATER USE,
Severn-Trent Water Authority, Birmingham (England).
J. E. Thackray, and G. G. Archibald.
Proceedings of the Institution of Civil Engineers, Part 1: Design and Construction, Vol 70, No 2, p 403-434, August, 1981. 9 Fig, 22 Tab, 16 Ref.

Descriptors: *Water use, *Industrial water, Water consumption, *Water demand, *Municipal water, Water reuse, Wastewater disposal, Economic aspects, *Severn-Trent Water Authority, Water prices, *England.

An extensive investigation of industrial and commercial water usse in the Severn-Trent Water Authority region involved a detailed survey of water use practices and policies of 3000 metered consumers. The proportions of piped water and directly abstracted water used by different industries are reported. Average annual metered consumption in the region rose from 550 million/liters per day in 1965 to 625 million liters per day in 1970, declined sharply to 525 million liters per day in 1977, and increased slightly to 575 million liters per day in the late 1970's. A table of water use classified by 18 different processes (cooling, product rinsing, gas scrubbing, etc.) in 16 industry categories (mining, food, chemicals, etc.) is presented. Water use per employees in manufacturing industries averaged 2065 liters per day, with wide variations. Domestic type water use by persons at work in industry averaged 96 liters per person per day, slightly less than the average household per capita consumption, 115-120 liters per day. Other tables and figures concern water use per unit of manufacturing output, water charges as a percentage of total costs, water saving schemes used in industry, elasticity of demand with respect to output, water recycling, average water use in service industries, and disposal of used water. This information base is usable by those involved in economic appraisals and in forecasting and design of facilities for water suppliers and consumers. (Cassar-FRC)

MASSACHUSETTS WATER SUPPLY PRIORITIES,
Massachusetts Dept. of Environmental Quality Engineering, Boston.
T. F. McLoughlin.
Journal of the New England Water Works Association, Vol 95, No 4, p 271-279, December, 1981. 2 Ref.

Descriptors: *Water supply, *Water resources development, *Massachusetts, *Water demand, Conservation, *Water quality, Industrial wastes, Aquifers, Financial aspects.

Water supply priorities are discussed, including impacts of hazardous waste on water supply, protection of existing and future aquifers, water conservation, regionalization, and budgetary constraints. Drinking water supplies in at least one-third of the communities in Massachusetts have been affected by organic chemical contamination to some degree, resulting in the closure of wells in 22 communities, with capacity losses averaging 40% and ranging as high as 100%. Increasing demands on groundwater supplies must be met with safeguards to protect the aquifers from further contamination. Fluctuations in groundwater levels are caused by a number of factors, including seasonal variations, changes in river and stream stages, various forms of withdrawal, and recharge. Tremendous efforts are underway to explore traditional and non-traditional sources of water supply. However, the need for conservation is clear. Water conservation programs can benefit water quality and quantity in various ways, including financial savings for the municipality as well as the individual homeowner. Regionalization is another name for sharing resources. This type of approach has great potential in solving supply and demand issues in the state of Massachusetts. Various factors to be considered include adequacy and reliability, quality, cost, legality and politics. (Baker-FRC)

A METHOD FOR ESTIMATING PEAK WATER DEMAND OF MULTIFAMILY RESIDENCES,
Institut National de la Recherche Scientifique, Sainte-Foy (Quebec).
B. Bobee, P. Boucher, and H. Demard.
Water Resources Bulletin, Vol 16, No 4, p 729-737, August, 1980. 2 Fig, 7 Tab, 15 Ref.

Descriptors: *Peak demand, *Domestic water, Apartments, *Water demand, *Statistical analysis, Water pressure.

Peak water demand for apartment residences of three or more units was estimated from the square root of the number of apartment units in the building and the cube root of water pressure. This relationship was obtained from statistical analysis of data from 17 apartment buildings, 3 to 41 apartments each, in Sainte-Foy, Quebec, using the Ridge-regression technique. The formula may be applied to the eastern U.S., where appliances, pressure conditions, and mean water demands are similar to those used in the study. Oversizing of meters and service lines increases maintenance costs, underregisters low demand, and requires a large initial investment. Undersizing the equipment leads to increases in friction loss, possible damage to the meter, and undercapacity. (Cassar-FRC)

DETERMINISTIC MODELS FOR PREDICTING RESIDENTIAL WATER CONSUMPTION,
Department of Transport and Works, Darwin (Australia).
N. A. Power, R. E. Volker, and K. P. Stark.
Water Resources Bulletin, Vol 17, No 6, p 1042-1049, December, 1981. 5 Fig, 4 Tab, 8 Ref.

Descriptors: *Water consumption, *Lawns, *Domestic water, *Model studies, Water demand, *Residential water, *Water use, Irrigation, Townsville, Australia.

Two deterministic models for forecasting residential water demand are presented. Lawn water requirements and in-house use are considered separately, then combined for a total predicted consumption. The in-house model requires the residence population, appliance ownership per residence, and water consumption of an appliance per use. It can simulate effects of changes in appliance ownership patterns, population distribution, appliance unit water use, and frequency of use. The lawn water model is a daily water balance model with a single soil moisture store. It operates in two phases, a drying phase through evaporation and transpiration and a wetting phase through rainfall and irrigation. Residential water consumption in Townsville, Australia, was modeled after a survey of a random sample of residences. In-house model results were 197 liters per capita per day; 205 liters per capita per day was obtained by measuring sewage flows. Simulations showed that increases of 100% in dishwasher ownership and garbage disposal ownership would increase average in-house consumption by 5.2% and 3.4%, respectively. Lawn water consumption was measured at five metered homes for 12 months. Simulated and actual water applied agreed within about 6 mm in the range of 669-885 mm seasonal irrigation water depths. (Cassar-FRC)

AN ECONOMIST'S VIEW OF DEMAND PROJECTIONS CONSIDERING CONSERVATION,
California Univ., Santa Barbara. Dept. of Economics.
W. D. Morgan.
Water Resources Bulletin, Vol 16, No 5, p 941-943, October, 1980. 2 Fig, 6 Ref.

Descriptors: *Water demand, *Water conservation, *Water use, *Economic aspects, Prices, Water management, Water supply, Mathematical studies, Elasticity of demand.

An approach was developed to clarify and elaborate on procedures for measuring water use undder alternative conservation specifications. An attempt was made to place the analyses in terms of traditional economic analysis. Using this analysis, the effects of conservation can be divided into two classes, pure conservation effects and pure demand management. The use of demand management to reduce quantity demanded operates through an increase in the price of water, which means individuals move up their demand curve and choose a smaller quantity. Conservation policies incorporate other factors that affect water usage, while holding the price constant. An increase in the conservation percentage reduces the quantity of water demanded. Providing information on techniques or technology is very important to enable users to choose the proper amount of water needed to meet their specified goals. Some instruments to meet these goals are under the control of the water agency, while others are not. However, the variable price is always under the control of the water purveyors. (Baker-FRC)

GROUND-WATER CONDITIONS IN THE UPPER VIRGIN RIVER AND KANAB CREEK BASINS AREA, UTAH, WITH EMPHASIS ON THE NAVAJO SANDSTONE,
Geological Survey, Salt Lake City, UT. Water Resources Div.
R. M. Cordova.
Available from Utah Dept. of Natural Res. Div. of Water Rights 231 East 400 South Salt Lake City, Utah 84111. Utah Department of Natural Resources Technical Publication No 70, 1981. 87 p, 18 Fig, 3 Plates, 23 Tab, 30 Ref.

Descriptors: *Groundwater, *Aquifer characteristics, *Water quality, *Well yield, Well data, Pumping, Drawdown, Groundwater recharge, Water level fluctuations, Surface-groundwater relations, Groundwater availability, Water supply, Water demand, Chemical analysis, Maps, *Utah, Virgin River basin, Kanab River basin, Navajo Sandstone.

The upper Virgin River and Kanab Creek basins area in south-central Utah includes about 1,300 square miles in the upper Virgin River basin and about 650 square miles in the upper Kanab Creek basin. The sparsely populated area contains large coal reserves. Water occurs in both the unconsolidated and consolidated rocks. Principal aquifers in the unconsolidated rocks include older stream-channel deposits, lower parts of alluvial fans, and stream-valley alluvium. The most important consolidated-rock aquifer is the Navajo Sandstone of Triassic and Jurassic age. Other consolidated-rock aquifers of note include the Shinarump Member of the Chinle Formation of Triassic age, sandstone strata of Cretaceous age, and the Wasatch Formation of Tertiary age. Groundwater recharge is derived chiefly from precipitation on the area and is estimated to average about 80,000 acre-feet per year. Discharge occurs chiefly as seepage to lower stream reaches and evapotranspiration; natural discharge is estimated to total at least 62,700 acre-feet per year. In addition, about 5,000 acre-feet per year discharges as underflow into Arizona; and in 1977, at least 3,300 acre-feet was withdrawn by wells. Chemical quality of ground water varies considerably with geologic source. Water in the Navajo Sandstone and Wasatch Formation is generally fresh, containing less than 500 mg/L of dissolved solids in most places. Water in the Chinle and Moenkopi Formations of Triassic age and the Carmel Formation of Jurassic age is generally saline, containing 1,000 to 3,000 mg/L of dissolved solids in most places. (USGS)

CLEAN WATER FOR THE THIRD WORLD,
Biswas and Associates, Oxford (England).
A. K. Biswas.
Water Supply and Management, Vol 5, No 6, p 401-415, 1981. 12 Ref.

Descriptors: *Drinking water, *Public health, *Developing countries, United Nations, *Costs, International Drinking Water Supply and Sanitation Decade, Water resources development, Sanitation, World Health Organization, Education, Water supply, Water quality standards, Investment, Institutional constraints, Political constraints, Reviews.

Current information on the availability and use of potable water in developing countries is critically

reviewed. Weaknesses in the World Health surveys of 1962, 1970, and 1975 are incomplete information (China and several other countries were not included), countries overestimating or underestimating the status of clean water supplies either to improve their images or to call attention to their difficulties, the intermittent nature of water service in may locations, and differences in enumeration method among countries. Provision of clean water without concurrent improvements in sanitation and health education is very ineffective. Western world water quality standards cannot be imposed on developing countries because significant percentages of existing water suplies would be automatically condemned and cost of equipment and personnel to maintain these high standards would be impractically high. The goal should be a variable standard to suit the locale, people, infection risks, and finances. Many cost estimates for the Decade have been calculated and revised. The currently accepted cost is $300 billion, considered by many to be a serious underestimate. There is small chance that the Decade will meet its goals. Constraints that must be overcome to ensure success are the lack of funds in the developing countries, the priorities of the individual countries, the lack of institutional infrastructure in many areas, lack of trained manpower, and lack of understanding of local conditions. THE RELATIONSHIP OF ACCESSIBLE SAFE WATER AND ADEQUATE SANITATION TO MATERNAL AND CHILD HEALTH--LOOKING FORWARD TO THE DRINKING WATER AND SANITATION DECADE,
Water and Sanitation for Health Project, Washington, DC.
R. B. Isely.
Water Supply and Management, Vol 5, No 6, p 417-424, 1981. 3 Fig, 1 Tab, 14 Ref.

Descriptors: *Drinking water, *Public health, *Social aspects, Sanitation, International Drinking Water and Sanitation Decade, Benefits, *Developing countries, United Nations, Diseases, Women, Children.

The chief beneficiaries of planned improvements in developing countries' water supplies and sanitation will be women and children. The average East African woman uses 9% of her daily caloric intake to obtain water for the household, up to 27% in hilly country. Diarrhea and its effects account for 30% of deaths in Third World children 0 to 4 years old. Waterborne diseases are responsible for undernutrition and many other ailments. Benefits from safe water supplies and improved sanitation are three fold: a better quality of life for women, reduced mortality and morbidity in young children, and the advantages that mother and child experience as a single bio-social unit (increased birthweight of infants, prolonged breastfeeding period, more time for child care, and a reduction in birth rate). WATER RESOURCES APPRAISAL FOR HYDROELECTRIC LICENSING: SEVIER LAKE BASIN, UTAH.
Federal Energy Regulatory Commission, San Francisco, CA. San Francisco Regional Office.
Appraisal Report, September, 1980. 61 p, 20 Fig, 10 Tab.

Descriptors: *Hydroelectric plants, *Water resources development, *Water demand, *River basin development, Irrigation, Flood control, Precipitation, Runoff, *Sevier Lake basin, *Utah.

The Sevier Lake basin is a major land-locked drainage basin covering all or portions of 11 counties in southwest Utah and a small portion of one county in Nevada. Average annual precipitation ranges from about 8 inches in the western desert to over 30 inches in the mountains. In spite of groundwater tables, which tend to recharge the Sevier River, losses to evapotranspiration aided by irrigation deplete flows in the river to the extent that runoff reaches Sevier Lake only during rare high flows. Approximately 400,000 acres (less than 5% of the total basin area) are irrigated. Fourteen small operating hydroelectric powerplants in the basin have a combined installed capacity of 6,260 kw, of which 77% is under license. The basin's hydroelectric plants produce about 34 gigawatt-hours annually which is about 5% of the forecasted 1978 energy requirement. There are two flood control projects in the basin. About 38% of the basin's installed hydroelectric capacity is developed in the 2,400 kw Upper Beaver plant. The Upper Beaver plant is in good condition and capable of being operated efficiently for a number of years in the future. It is not considered to be economically justified for the company to make repairs for resumed power production at the Lower Beaver plant. Water resource projects which have been considered for development include: a land rehabilitation program; a water diversion project; two pumped storage projects, and two low-head hydroelectric powerplants. THE WELSH APPROACH TO WATER RECREATION,
S. Le Lievre.
Water, No 42, p 29-31, 1982. 3 Fig.

Descriptors: *Water use, *Recreation, *Water demand, Boating, Fishing, Lakes, Reservoirs, *Wales, Regulations.

The Welsh Water Authority Strategic Plan for Waterspace Recreation and Amenity was recently released. Representative bodies of users and individuals with interests in countryside conservation and wildlife protection have given unequivocal approval and support to the authority's proposals, which took six years to complete. Uppermost in the minds of the authority is the conservation of the countryside in which the visible assets of water space are located. Much of the time taken in preparing the master plan was occupied in consultations with all types of users, in order to search for practical solutions to possible areas of conflict or clashes of interest. THE SEVEN-TRENT STUDIES OF INDUSTRIAL WATER USE,
Severn-Trent Water Authority, Birmingham (England).
J. E. Thackray, and G. G. Archibald.
Proceedings of the Institution of Civil Engineers, Part 1: Design and Construction, Vol 70, No 2, p 403-434, August, 1981. 9 Fig, 22 Tab, 16 Ref.

Descriptors: *Water use, *Industrial water, Water consumption, *Water demand, *Municipal water, Water reuse, Wastewater disposal, Economic aspects, *Severn-Trent Water Authority, Water prices, *England.

An extensive investigation of industrial and commercial water usse in the Severn-Trent Water Authority region involved a detailed survey of water use practices and policies of 3000 metered consumers. The proportions of piped water and directly abstracted water used by different industries are reported. Average annual metered consumption in the region rose from 550 million/liters per day in 1965 to 625 million liters per day in 1970, declined sharply to 525 million liters per day in 1977, and increased slightly to 575 million liters per day in the late 1970's. A table of water use classified by 18 different processes (cooling, product rinsing, gas scrubbing, etc.) in 16 industry categories (mining, food, chemicals, etc.) is presented. Water use per employees in manufacturing industries averaged 2065 liters per day, with wide variations. Domestic type water use by persons at work in industry averaged 96 liters per person per day, slightly less than the average household per capita consumption, 115-120 liters per day. Other tables and figures concern water use per unit of manufacturing output, water charges as a percentage of total costs, water saving schemes used in industry, elasticity of demand with respect to output, water recycling, average water use in service industries, and disposal of used water. This information base is usable by those involved in economic appraisals and in forecasting and design of facilities for water suppliers and consumers. (Cassar-FRC)

MASSACHUSETTS WATER SUPPLY PRIORITIES,
Massachusetts Dept. of Environmental Quality Engineering, Boston.
T. F. McLoughlin.
Journal of the New England Water Works Association, Vol 95, No 4, p 271-279, December, 1981. 2 Ref.

Descriptors: *Water supply, *Water resources development, *Massachusetts, *Water demand, Conservation, *Water quality, Industrial wastes, Aquifers, Financial aspects.

Water supply priorities are discussed, including impacts of hazardous waste on water supply, protection of existing and future aquifers, water conservation, regionalization, and budgetary constraints. Drinking water supplies in at least one-third of the communities in Massachusetts have been affected by organic chemical contamination to some degree, resulting in the closure of wells in 22 communities, with capacity losses averaging 40% and ranging as high as 100%. Increasing demands on groundwater supplies must be met with safeguards to protect the aquifers from further contamination. Fluctuations in groundwater levels are caused by a number of factors, including seasonal variations, changes in river and stream stages, various forms of withdrawal, and recharge. Tremendous efforts are underway to explore traditional and non-traditional sources of water supply. However, the need for conservation is clear. Water conservation programs can benefit water quality and quantity in various ways, including financial savings for the municipality as well as the individual homeowner. Regionalization is another name for sharing resources. This type of approach has great potential in solving supply and demand issues in the state of Massachusetts. Various factors to be considered include adequacy and reliability, quality, cost, legality and politics. (Baker-FRC)

A METHOD FOR ESTIMATING PEAK WATER DEMAND OF MULTIFAMILY RESIDENCES,
Institut National de la Recherche Scientifique, Sainte-Foy (Quebec).
B. Bobee, P. Boucher, and H. Demard.
Water Resources Bulletin, Vol 16, No 4, p 729-737, August, 1980. 2 Fig, 7 Tab, 15 Ref.

Descriptors: *Peak demand, *Domestic water, Apartments, *Water demand, *Statistical analysis, Water pressure.

Peak water demand for apartment residences of three or more units was estimated from the square root of the number of apartment units in the building and the cube root of water pressure. This relationship was obtained from statistical analysis of data from 17 apartment buildings, 3 to 41 apartments each, in Sainte-Foy, Quebec, using the Ridge-regression technique. The formula may be applied to the eastern U.S., where appliances, pressure conditions, and mean water demands are similar to those used in the study. Oversizing of meters and service lines increases maintenance costs, underregisters low demand, and requires a large initial investment. Undersizing the equipment leads to increases in friction loss, possible damage to the meter, and undercapacity. (Cassar-FRC)

LIBRARY U. OF I.- URBANA-CHAMPAIGN

A MUNICIPAL WATER SUPPLY INVESTMENT PROBLEM IN RHODE-ISLAND,
Western Washington Univ., Bellingham. Dept. of Economics.
R. Frye, and J. W. McFarland.
Water Resources Bulletin, Vol 16, No 1, p 31-35, February, 1980. 10 Ref.

Descriptors: *Water demand, *Water conservation, *Economic aspects, Computers, Water resources development, Resources development, *Rhode Island, Water supply, Water supply development, Water requirements, Model studies, Pricing.

Two approaches are considered to a residential water supply problem being experienced in Rhode Island. The first approach is a benefit maximization model incorporating price sensitive water demand as the basis for measuring system benefits. This is contrasted with a 'requirements' approach, which is a cost minimization model constrained b the requirement to provide a minimum quantity per household. To reconcile the differences between the results of the two approaches, a modification is made in the benefit-maximization approach to include peak demand considerations. The study focuses on Newport, Middletown, and Portsmouth, Rhode Island, located on Aquidneck Island in Narragansett Bay. Results indicate that a requirements approach can lead to findings similar to a benefit maximization model incorporating price sensitive demand. Incorporating price sensitive demand also leads to ambiguous results due to not knowing which demand function to use as a measure of benefits or how to construct such a function. The findings do confirm that dynamic programming is a useful way of formulating the intertemporal investment-production problem in different sources of supply and/or capital components exhibiting differing economies of scale. The method allows explicit consideration of the tradeoffs between the costs of periods of excess capacity and economies of scale for a number of components. The choice of an objective function requires flexibility; benefit maximization and cost minimization can lead to similar or dissimilar results, depending on the flexibility of the analyst and the model. WATER MANAGEMENT IN ONTARIO,
Ontario Ministry of the Environment, Toronto.
S. E. Salbach, and R. P. Dennis.
Water Resources Bulletin, Vol 16, No 4, p 621-262, August, 1980.

Descriptors: *Water management, *Regulations, *Water policy, *Water quality standards, Management, *Ontario, Groundwater, Surface water, Effluent standards, Water allocation, Water pollution control.

The Ontario Ministry of the Environment revised its 1970 guidelines for water quality management in 1976 as a response to changes in the social and economic background, advances in technology, and philosophical attitudes toward water management. Goals, objectives, and policies to implement the goals are given for management of surface water quality and quantity and groundwater quality and quantity. For example, the goal for surface water quality is to ensure that the surface waters of the province are of a qality which is satisfactory for aquatic life and recreation. The policies for implementation concern areas with water quality better than the objectives, areas with water quality not meeting the objectives, effluent requirements, hazardous subsurfaces, and mixing zones. The revised approach involves imposition of legally enforceable effluent requirements on a case-by-case basis rather than having province-wide effluent standards. Five working groups are developing the necessary detailed implementation procedures. (Cassar-FRC)

OBJECTIVES AND CONSTRAINTS IN FEDERAL WATER RESOURCES PLANNING,
Policy Sciences Associates, Boulder, CO.
W. B. Lord.
Water Resources Bulletin, Vol 17, No 6, p 1060-1065, December, 1981. 6 Ref.

Descriptors: *Planning, *Decision making, *Political constraints, Water Resources Council, Water resources development, Economic development, Environmental quality, *Water policy, Public participation.

The Water Research Council's 1973 'Principles and Standards' states that plans should be formulated to reflect national, regional, state, and local needs or problems consistent with the objectives of improvements in national economic development and environmental quality. There is no specified approach to reconciling national objectives with local needs and problems. Increasingly, the approach has been to plan with national objectives as the first consideration. This is not the most practical or desirable method, partly because the national objectives are general and abstract. Many conflicts between the federal government and local groups have arisen over water resources development projects. A more satisfactory planning method is to formulate plans for solving a specific local problem and then consider the restraints imposed by the national objectives. Public participation on the local level is recommended. (Cassar-FRC)

THE ADOPTION OF MUNICIPAL WATER CONSERVATION: AN UNLIKELY EVENT,
Oklahoma State Univ. Stillwater. Dept. of Economics.
R. L. Moomaw, and L. Warner.
Water Resources Bulletin, Vol 17, No 6, p 1029-1034, December, 1981. 1 Tab, 11 Ref.

Descriptors: *Water conservation, *Institutional constraints, *Pricing, *Municipal water, Water rates, Planning, Nonstructural alternatives, Water policy, Profit, Political aspects.

Municipal water utilities are unlikely to voluntarily adopt water conservation practices which reduce net revenues, even if they are beneficial in the long term. Institutional changes are suggested. Decisions involving decreases of revenues (pure conservation measures such as new plumbing codes, education, and retrofitting) should be removed from the water enterprises jurisdiction. Subsidies to the water company for improved management practices such as meter repair and leak control may increase chances for adoption of these conservation measures, even though they decrease revenues. Conservation pricing (overall rate increase, summer surcharges, and flat rates) increase water company revenues but may create illegal or unpopular profits. Laws can be changed to allow use of such profits for property tax relief or other acceptable programs. A study of five Texas and Louisiana cities illustrates some of these alternatives. All these cities have had recent water increases of 10% to 35%, and all but one had sewer increases from 35% to 140%. There is also a trend toward conservation by better management and maintenance. Only one city adopted measures that cost the utilities money and decreased short-term revenues. (Cassar-FRC)

THREE IMPORTANT COURT DECISIONS,
Cook Coll., New Brunswick, NJ.
W. Goldfarb.
Water Resources Bulletin, Vol 17, No 6, p 1097-1098, December, 1981.

Descriptors: *Judicial decisions, *Landfills, *Effluent standards, Water law, *Water management, Chemical wastes, Waste disposal, Cost-benefit analysis, Permits, *Illinois.

Three court decisions of concern in water management are reported. In the Village of Wilsonville v. SCA Services, Inc., the Illinois Supreme Court affirmed a lower court decision to close a hazardous waste landfill located in a coal mine subsidence zone because it threatened groundwater quality. The argument that the landfill site and all disposals had state EPA approval were rejected because permits were allegedly based on inaccurate data. In Issac Walton League v. Marsh a federal court of appeals refused to review the cost-benefit analysis for the Army Corps of Engineers Locks and Dam 26 Project on the Mississippi River near Alton, Illinois, thus allowing the project to preceed as authorized. The American Paper Institute v. EPA case invalidated the Environmental Protection Agency regulations for industrial effluent discharges based on best conventional pollutant control technology (BCT). It is likely that little progress beyond Phase I, best practicable technology (BPT), will be seen in the near future. (Cassar-FRC)

THE WINTERS DECISION AND INDIAN WATER RIGHTS--A MYSTERY REEXAMINED,
California Univ., Los Angeles. Dept. of History.
N. Hundley.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-211525, Price codes: A03 in paper copy, A01 in microfiche. March, 1982. 31 p, 77 Fig. OWRT A-059-CAL(3).

Descriptors: *Legal aspects, *Water rights, *Judicial decisions, *History, *Indian reservations, Western United States, Semiarid lands.

Water is the natural resource of greatest concern in western American, an area of few rivers, sparse rainfall, and monumental struggles over the precious commodity. Joining increasingly in the struggles have been Native Americans, most of whose reservations and reservation population are found in the driest portions of the region. No less concerned are non-Indians whose cities, industries, and farms are already using most of the West's water. At the heart of these controversies, both past and in-th-making, are differences over a 1908 decision rendered by the United States Supreme Court in Winters v. United States. That decision announced for the first time the existence of an Indian water right, but the meaning of the court's action has become clouded in debate which has exacerbated conflicts between Indians and non-Indians and created a crisis of national significance. For more than half a century, attorneys, legal scholars, and historians have quarreled over the meaning to the Winters decision with three issues in particular dominating their differences: the quantum or volume of the Indian right, the legitimate uses to which the water guaranteed by the right can be put, and the priority of the right in relation to the rights of non-Indians desirous of the same water sources. Careful examination of published documents and heretofore overlooked manuscript materials helps to clarify the intentions of the Winters court and to shed light on the ongoing disputes over the Indian water right. (Snyder-California)

WATER RIGHTS, ALLOCATION, AND CONFLICTS IN THE TONGUE RIVER BASIN, SOUTHEASTERN MONTANA,
Ohio Wesleyan Univ., Delaware. Dept. of Geography and Geology.
D. H. Kickox.
Water Resources Bulletin, Vol 16, No 5, p 797-803, October, 1980. 3 Fig, 1 Tab, 19 Ref.

Descriptors: *Water law, *Montana, *Water resources development, *Water rights, Water requirements, Legal aspects, Water use, Water policy, State jurisdiction, *Water demand, Water supply, Riparian rights, Reservoir storage, Irrigation requirements, Future planning, Coal, *Tongue River basin.

The extensive development of coal deposits in Southeastern Montana's Tongue River basin has created a great demand on the area's water resources. In some areas not enough water is available to meet demands, while in other cases, even though water is in abundance, it may not be legally available due to a new Montana water allocation system, Indian lawsuits, or state policy toward water resource development. Some energy proj-

ects threaten to dewater the river, degrade water quality and endanger aquatic ecosystems. The Montana Water Use Act was enacted in 1973 to end the uncertainties existing in Montana water law by requiring final allocation and adjudication of the state's waters. In 1974, the Water Moratorium Act was passed to allow the state time to plan for future water use. In 1978, plans were made for the Tongue River Reservoir, which will soon be replaced by a larger dam and reservoir. Irrigation districts will be allotted all the water they have requested. The Fish and Game Department has requested enough water to maintain instream flows. Processing of industrial applications for water began in 1979. The Montana Water Storage Company and the Water Reserve Company have both requested large diversions that cannot be met by the available water in the Tongue River. Industrial allotments will probably continue to take a second place to preferred agricultural water uses in Montana. (Geiger-FRC)

DEVELOPMENT OF FEDERAL RESERVE RIGHTS,
Nevada Univ. System, Reno. Dept. of Civil Engineering.
J. W. Bird.
Water Resources Bulletin, Vol 16, No 5, p 837-842, October, 1980.

Descriptors: *Federal jurisdiction, *Water rights, *Water law, *Arid zone hydrology, *Reservation doctrine, Flood control, Water management, Legal aspects, Riparian rights, Water policy, Water supply, Water use, Navigable waters, Arid lands.

States in arid regions are concerned over the federal reserved rights termed 'Indian Rights to Water', which include such concepts as navigation improvement and flood control plans. Recently a large number of lawsuits concerning water based on the Winters' Doctrine been filed in arid states. The protection of federal reserved water rights can be seen in such landmark cases as the U.S. vs. Rio Grande Dam and Irrigation Company (1899), Winters vs. U.S. (1908), Federal Power Commission vs. Oregon (1955), Arizona vs. California (1963), and U.S. vs. District Court for Eagle County (1971). The existing lawsuits on surface water sources such as the one now on appeal involving reserved federal rights on the Truckee River have promulgated two standards for deciding on the use of reserved waters. Those uses needed to fulfill the purposes contemplated when the reservation was created will be considered under one plan, while all possible uses, including those which appear in the future, without reference to the purposes for which the reservation was created, will form a second plan for reserved water use. The first plan allows a rapid quantification of the reserved water rights to identify and protect a certain amount of water from others. In the second case, the Indians' rights would remain uncertain, and the courts may be able to force the Indians to accept compensation for their claim if no water is available. (Geiger-FRC)

NEW FEDERAL WASTEWATER DISCHARGE STANDARDS IN GERMANY,
Ministry of the Interior, Berlin (Germany, F.R.).
H. Hornef, and S. Kanowski.
Effluent and Water Treatment Journal, Vol 21, No 11, p 510, 511, 513, 514, November, 1981. 2 Tab, 2 Ref.

Descriptors: *Wastewater disposal, *Regulations, Standards, *Federal jurisdiction, *Industrial wastes, Water quality, *Water pollution control, *West Germany.

The federal government in Germany has enacted two general laws which emphasize the principle of precaution and the need for those who do the polluting to pay for the cost of cleanup. The Wastewater Charges Act rules that a fee has to be paid for discharging wastewater into receiving waters. This charge may be reduced by 50% if the minimum quality requirements are met. The minimum requirements are compulsory everywhere in the Federal Republic of Germany and are independent of the state of the receiving waters. These requirements are generally emission standards in the form of concentrations and/or load of pollutants specific for products. In 1977 the federal government established 50 task forces to develop proposals for minimum requirements on an industry-by-industry basis. The most important pollutants/parameters for which minimum requirements are to be fixed are those for which a wastewater charge has to be paid, including settleable solids, chemical oxygen demand, cadmium, mercury, and toxicity for fish. In specific branches requirements will be set for biochemical oxygen demand, hydrocarbons, phenols, cyanide, heavy metals, halogenated hydrocarbons, sulfide, ammonia, fluoride, phosphorus, and total suspended solids. State authorities will set requirements for pH and temperature parameters. (Baker-FRC)

EXPERIENCES WITH EEC GUIDELINE 75/440 ON THE QUALITY OF SURFACE WATERS FOR DRINKING WATER PRODUCTION IN THE MEMBER STATES (ERFAHRUNGEN MIT DER EG RICHTLINIE 75/440 UBER DIE QUALITAT VON OBERFLACHENWASSER FUR DIE TRINKWASSERGEWINNUNG IN DEN MITGLIEDSTAATEN).
GWF-Wasser/Abwasser, Vol 122, No 12, p 555-560, 1981. 5 Fig. English Summary.

Descriptors: *Legal aspects, *Water quality standards, *European Economic Community, International law, Drinking water, Potable water, Surface water, Water quality, Lead.

The European Economic Community (EEC) Council of Ministers' guidelines on surface water quality for drinking water, published in 1975, is critically reviewed. This guideline had a dual goal of preventing water pollution and protecting public health. Some European water managers have expressed the opinion that this guideline offers more hindrance than help. Implementation in many countries has placed the burden of assuring acceptable source quality on the water supply enterprise and has failed sufficiently to emphasize pollution prevention. Some water obtainment treatment techniques widely used in Europe are not covered by the guideline. No encouragement is provided for improving water quality beyond minimum standards. Not all of the recommended methods and standards are adequately defined. Since this guideline is in the process of being adopted in legislation of the EEC member countries, it is advisable that these problems be resolved as soon as possible. (Carroll-FRC)

THE FINANCING OF PRIVATE SMALL SCALE HYDROELECTRIC PROJECTS.
Franklin Pierce Law Inst. Center, Concord, NH.
For primary bibliographic entry see Field 6B.
W82-04633

A MANUAL FOR DEVELOPMENT OF SMALL SCALE HYDROELECTRIC PROJECTS BY PUBLIC ENTITIES.
Energy Law Institute, Franklin Pierce Law Inst. Center, Concord, NH.
Available from the National Technical Information Service, Springfield, VA 22161 as DOE/CE/04934-45, Price codes: A03 in paper copy, A01 in microfiche. DOE/CE/04934-45, March, 1981. 39 p, 1 Tab.

Descriptors: *Hydroelectric plants, *Legal aspects, *Economic aspects, *Local givernments, Financing, Permits, Licensing, Dams, Construction, Feasibility studies, Legislation.

This manual is designed to provide guidance to towns, cities, counties and other political subdivisions which are interested in undertaking or participating in small scale hydroelectric (SSH) development within or close to their territorial boundaries. A SSH project is of 25 to 30 MW or less and utilizes an existing dam or structure or utilizes the site characteristics of partially breached dams or structures. Since 1978 new federal legislation has removed some of the obstacles to SSH projects and has created substantial incentives for development. The hydroelectric development process can be braken down into the following sequential steps: reconnaissance study: feasibility study; permits, licensing, and exemptions study; engineering design; power purchase negotiations; construction; and operation. Every political subdivision must examine its charter or enabling legislation in order to determine whether it is authorized to proceeed with development of a SSH project. Assuming the requisite authorization exists, the political subdivision may choose to be the sole owner, developer and operator, in which case the financing and other arrangements are straight-forward. Assuming state or local law permits, the political subdivision may consider joint development with a private development firm, the local investor owned utility or another political subdivision. Disposition of a site owned by a political subdivision can take a variety of forms: outright sale at auction, sale of an option to purchase, a lease resulting from a bidding system, or a management and development contract resulting from a competitive proposal system. Since at least 80% of the annual cost of a hydroelectric project consists of interest payments and capital amortization expenses, it is important to select a financing strategy that minimizes the cost of financing the project. APPLICATION OF THE AREA OF REVIEW CONCEPT,
Robert S. Kerr Environmental Research Lab., Ada, OK.
J. T. Thornhill, T. E. Short, and L. Silka.
Ground Water, Vol 20, No 1, p 32-38, 1982. 3 Fig, 3 Tab, 8 Ref.

Descriptors: *Injection wells, *Water quality control, *Mathematical studies, *Computer models, *Oil wells, *Hydrostatic pressure, Groundwater management, Water quality management, Model studies, Digital computers, Aquifers, Groundwater movement, Drinking water, Injection wells, Regulations.

Underground Injection Control regulations require that the issuers of permits determine, within an 'area of review', whether a proposed injection operation has a potential for contaminating underlying or overlying aquifers through faults, wells, or other conduits that permeate the injection zone. The 'area of review' is defined as that area the radius of which is the lateral distance from an injection well or injection well pattern in which the pressure change due to injection operations may cause the migration of the injection and/or formation fluid into an underground drinking water supply. It is thus the area around an injection well where, during injection, the hydrostatic head of the formation fluid in the injection zone is equal to or greater than the hydrostatic head of underground sources of drinking water. A Theirs equation may be used to determine the zone of endangering influence to define the area of review. The concept was applied to Texas oil fields in Anderson County, Andrews County and Refugio County, where active injection wells already existed and sufficient data was available to determine the area of review. The Warner analytical method for determining pressure buildup and a programmable desk calculator and digital computer were used in this exercise. In studying areas that have numerous injection wells discharging into the same zone, it was suggested that the effect of all the wells on the pressure buildup be considered. (Geiger-FRC)

RECENT DEVELOPMENTS IN COLORADO GROUNDWATER LAW,
Davis, Graham and Stubbs, Denver, CO.
F. Hannay.
Denver Law Journal, Vol 58, No 4, p 801-823, 1981. 194 Ref.

Descriptors: *Water law, *Wells, *Water rights, *Colorado, *Groundwater management, *State jurisdiction, *Appropriation, Legal aspects, Riparian

LIBRARY U. OF I.- URBANA-CHAMPAIGN

rights, Water use, Tributaries, Surface water, Water allocation, Resources development, Water management, Equitable apportionment, Permits.

The developments in Colorado water law with respect to both tributary and nontributary groundwater are reviewed. Tributary groundwater is defined as any surface and underground water of the state that would affect the rate of flow of the natural stream into which it flows over a period of forty years or less. A case in which the use of groundwater for two wells would have affected the rate and flow of the Cache La Poudre River helped establish the definition of tributary groundwater. If a well's operation would not affect the flow in a stream until one hundred years or more after the commencement of pumping, such a water supply would be defined as nontributary groundwater. In 1965, House Bill 1066 gave the state engineer the authority to control existing and new wells in Colorado. The 1969 Water Rights Determination and Administration Act served to implement and refine the doctrine of maximum water utilization while preserving vested rights. Recent court cases which sought to clarify the 1969 Act were unsuccessful at this task. The Colorado Supreme Court must still decide if nontributary groundwater can be appropriated, and, if so, how and by whom. (Geiger-FRC)

BUBB V. CHRISTENSEN: THE RIGHTS OF THE PRIVATE LANDOWNER YIELD TO THE RIGHTS OF THE WATER APPROPRIATOR UNDER THE COLORADO DOCTRINE,
E. A. Rada.
Denver Law Journal, Vol 58, No 4, p 825-836, 1981. 88 Ref.

Descriptors: *Water rights, *Colorado, *Appropriation, *State jurisdiction, *Land tenure, Water law, Riparian rights, Legal aspects, Water use, Water allocation, Water management, Land rights.

The Colorado Doctrine, which was developed to permit maximum utilization of water, implies that a water right may be acquired separate from the land. This negates the importance of trespass in the determination of a valid water right as seen in the case of Bubb vs. Christensen. The private landowner's right to be protected against trespass is subordinate if the trespasser can clearly demonstrate his intent to appropriate water on or adjacent to another's property. The landowner's recovery will be limited only to damages rather than to denial of the appropriator's right to use the diverted water. If it can be demonstrated that the appropriator did not put the water to good use and wrongfully took the owner's land, then the landowner may obtain relief in a court of general jurisdiction in an action for trespass. The court decision handed down in Bubb vs. Christensen suggests that a private landowner's property may be taken by one holding a conditional water right without first making compensation to the owner. The proposed oil shale industry in Colorado will have a significant impact on the limited water resources of the state in two vital respects - depletion of water quantity and degradation of water quality. Oil shale companies will compete with agriculture, municipalities, other industries and recreation for the state's limited water supplies and will face environmental concern over water systems already polluted by existing users and by nature. General information of a technical nature is presented about oil shale geology and technology in order to form a framework for the legal issues related to water for oil shale development. The paper considers water availability, geology of oil shale formation, technologies for shale development, water requirements of the industry, and anticipated water quality impacts. This background will facilitate understanding of the legal problems inherent in the acquisition and use of Colorado water. A multitude of legal problems will surface as the oil shale industry continues to seek adequate and dependable water supplies. These problems will be further compounded by the labyrinth of federal regulations and by Colorado's specialized water law system. Ultimate resolution of these legal questions by the courts will significantly influence Colorado's role in helping the United States achieve energy independence. (Baker-FRC)

COVERING DISTRIBUTION STORAGE, PANEL DISCUSSION: STATE OF THE ART,
New Hampshire Water Supply and Pollution Control Commission, Concord.
S. W Leavenworth.
Journal of the New England Water Works Association, Vol 95, No 4, p 245-247, December, 1981.

Descriptors: *Reservoirs, *Water pollution prevention, Water supply development, Surface water, Water pollution sources, *Legal aspects, Public health, *Concord, *New Hampshire.

Problems encountered during efforts to secure a covering for a storage reservoir in the City of Concord, New Hampshire, are reviewed. In the summer of 1969 high levels of coliform bacteria were noted in water samples collected from the high service portion of the distribution system, while samples from other parts of the system were of a much better quality. The high service portion was served by a ground level uncovered storage reservoir with a capacity of about two million gallons. Application to install a cover was granted, but when funding finally became available, the priority of other projects was put above the reservoir cover and the project did not begin as planned. After a hearing before the Commission, the City was ordered to install a cover. The objections which the city had presented stemmed mainly from an epidemiologist's report that there had been no statistical evidence linking waterborne disease outbreaks to uncovered reservoirs. However, this approach to reasoning disregards the entire concept of prevention. There is also ample evidence that the various improvements in water treatment and in knowledge of water supply and distribution have reduced the incidence of waterborne disease outbreaks dramatically. Eventually in the City of Concord, the technical aspects took second place to the legal approach, as the order of the Commission was eventually appealed by the City to the State Supreme Court. In the final judgment, the Commission won, but more on legal grounds than on health and safety evidence. (Baker-FRC)

AUCTIONS AND ALTERNATIVE PROCEDURES FOR ALLOCATING POLLUTION RIGHTS,
Texas Univ. at Austin. Dept. of Economics.
R. M. Lyon.
Land Economics, Vol 58, No 1, p 16-32, February, 1982. 1 Fig, 2 Tab, 25 Ref.

Descriptors: *Water pollution control, *Legal aspects, *Water rights, Industrial wastes, *Regulations, Effluent charges, Effluent limitations.

This paper considers both potential strategic behavior of dischargers bidding for rights and price-taking behavior. Particular attention is given to examining the types of auction procedures that could be used to implement rights sales by the government, if the approach of government sales is adopted. A special type of auction, a type of roves mechanism, that discourages strategic bidding by dischargers is contrasted with auctions that use a single clearing price as a method for government sales. Regulatory procedures are considered, as they represent a standard against which programs involving transferable rights can be compared. Under the single-price auction rights would be sold to the highest bidders for a price that could represent either the lowest accepted bid or the highest rejected bid. A discriminating auction is designed specifically to eliminate dischargers' incentives for strategic bidding. Based on both theoretical and practical considerations, it is concluded that there is a fundamental trade-off between reducing the financial burden of rights purchases and eliminating the incentives for strategic behavior. Very few dischargers in either of the two case studies presented would have lowered expenses under government sales of rights rather than under uniform treatment regardless of whether sales are by a single-price or incentive-compatible auction. The simulations also suggest that there may be opportunities for strategic behavior under nonincentive-compatible procedures because of small numers of dischargers. The rights allocation approach of free distribution followed by exchange may present the most desirable package of features. (Baker-FRC)

FLOOD HAZARD IDENTIFICATION AND FLOOD PLAIN MANAGEMENT ON ALLUVIAL FANS,
Army Engineer Div. North Pacific, Portland, OR.
L. M. Hagura, and D. E. Wood.
Water Resources Bulletin, Vol 16, No 1, p 56-62, February, 1980. 8 Fig, 6 Ref.

Descriptors: *Flood control, *Alluvial fans, Alluvial plains, Sedimentary structures, Floods, United States, Land management, *Flood plains, Flood plain management, California.

This paper focuses on a special study procedure that the Federal Insurance Administration (FIA) has developed and is requiring its flood insurance study contractors to utilize for identifying alluvial fan (AF) zones. The need for an appropriate AF hazard identification procedure was dramatically emphasized by the passage of Tropical Storm Kathleen over the desert areas of Southern California in September of 1976. The pattern of flood damage was more typical of midwestern tornado damage, with certain localities extremely hard hit and other adjacent communities experiencing little or no structural damage. The basic cause of the substantial flood damage was a failure on the part of the local planning and building officials and developers to recognize the true degree of flood hazard that exists on alluvial fans. The procedure is understandably crude compared to other flood hazard identification techniques applied to more conventional flood problems. (Baker-FRC)

MODELING THE ENVIRONMENTAL EFFECTS OF A NAVIGATION CHANNEL IN A TIDAL BAY,

Rice Univ., Houston, TX. Dept. of Environmental Science and Engineering.
P. B. Bedient, R. W. Hall, and C. J. Newell.
Water Resources Bulletin, Vol 16, No 5, p 881-886, October, 1980. 5 Fig, 4 Tab, 13 Ref.

Descriptors: *Navigation canals, *Environmental effects, *Model studies, Mathematical models, Salinity, Simulation, Channels, Tidal basins, Hydrologic models, *Tidal waters, Bays, Louisiana, Vermilion Bay, New Iberia.

This paper documents the use of a mathematical bay model to predict the environmental impacts of a proposed navigation channel from the Port of New Iberia, Louisiana, to the Gulf of Mexico through Vermilion Bay. Although these large bays cover an area of 293,895 acres, they are rather shallow, with depths averaging 5 to 7 feet. Models wer used to predict the changes in flow and salinity in the bay system under a variety of flow, wind, and channel conditions. The major assumptions in the model were that the bay is vertically well mixed, significant variations in depth from cell to cell do not occur at more than a few places in the bay, Atchafalaya inflows do not appreciably alter the tidal variation input to West Cote Blanche Bay, salinities are based on tidally averaged flows and do not represent actual peaks and lows within a tide cycle, and source salinities and source tides are assumed to correspond, although actual data were not simultaneously available for both. The model predicted that average salinity in the Vermilion Bay system would decrease with both high south winds and high fresh water inflows when compared to standard conditions. With a navigation channel incorporated in the model, average bay salinities were predicted to be lower for all three simulation cases. This project also pointed out the crucial role of complete input data in the effective appraisal of major projects such as the Vermilion Bay channel. Environmental impacts of major projects do not always follow the course of similar projects, as seen by the Vermilion Bay model results when compared to other channels constructed on the Gulf Coast. SIMULATED HYDROLOGIC EFFECTS OF POSSIBLE GROUND-WATER AND SURFACE-WATER MANAGEMENT ALTERNATIVES IN AND NEAR THE PLATTE RIVER, SOUTH-CENTRAL NEBRASKA,
Geological Survey, Denver, CO. Water Resources Div.
A. W. Burns.
Geological Survey Open-File Report 81-1116, 1981. 41 p, 21 Fig, 5 Tab, 10 Ref, Append.

Descriptors: *Surface-groundwater relations, *Wildlife habitats, *Water management, Wetlands, Aquifers, Groundwater recharge, Streamflow, Irrigation, *Nebraska, *Platte River.

Digital computer models were developed and used to simulate the hydrologic effects of hypothetical water-management alternatives on the wetland habitat area near Grand Island, Nebr. Areally distributed recharge to and discharge from the aquifer system adjacent to the Platte River between Overton and Grand Island were computed for four hypothetical water-management alternatives. Using stream-aquifer response functions, the stream depletions resulting from the different alternatives ranged from 53,000 acre-feet per year for increased surface-water irrigation to 177,000 acre-feet per year for increased ground-water pumpage. Current conditions would result in stream depletions of 125,000 acre-feet per year. Using the relationship between discharge and river stage, frequency curves of the stage in the river near the wildlife habitat area were computed using a 50-year sequence of historical streamflow at Overton, minus the stream depletions resulting from various management practices. For the management alternatives previously discussed, differences in the stage-frequency curves were minimal. For comparative purposes, three additional water-management alternatives whose application would change the incoming streamflow at Overton were simulated. Although in these alternatives the amounts of water that were diverted or imported were similar to the amounts in the previous alternatives, their effects on the stage-frequency curves were much more dramatic. INERTIA AND RECOVERY: AN APPROACH TO STREAM CLASSIFICATION AND STRESS EVALUATION,
Maryland Univ., Frostburg. Appalachian Environmental Lab.
J. R. Stauffer, Jr., and C. H. Hocutt.
Water Resources Bulletin, Vol 16, No 1, p 72-78, February, 1980. 2 Fig, 3 Tab, 36 Ref.

Descriptors: *Stream classification, *Stress, *Fish, Classification, Elastic properties, *Ecosystems, Biological communities, Water management, Streams, Inertia.

The feasibility of using a system based on inertia and elasticity was examined, and these concepts were applied to fish data collected by Hocutt and Stauffer on Conowingo Creek. For the purposes of the study, Conowingo Creek was divided into four sections based on stream order and gradient. The concept of inertia and elasticity was able to be used to formulate a stream classification system, which can predict the amount of stress a particular system can assimilate and the potential of a system to recover if and when the assimilative capacity is exceeded. In this example a stress at any of the upstream locations would probably affect downstream areas, and therefore both inertia and elasticity indices would be more realistic if calculated for separate tributaries of a major drainage basin. These types of analyses must be applied to various ecosystems using different phyletic groups before this system can be fully evaluated. In this study fish were used because they occupy the top of the food chain in most stream systems, and thus their presence implies the presence of many other phyletic groups. Fish also pass through most, if not all trophic levels above the primary producer stage as their development proceeds from larvae through adults. Inertia appeared to be a more useful concept than elasticity for predicting the effects of potential stress. The relationship between structural and functional redundancy and their influences on the inertia index are discussed. (Baker-FRC)

MAN-MADE STORAGE OF WATER RESOURCES-A LIABILITY TO THE OCEAN ENVIRONMENT. PART I,
Bedford Inst. of Oceanography, Dartmouth (Nova Scotia).
H. J. A. Neu.
Marine Pollution Bulletin, Vol 13, No 1, p 7-12, January, 1982. 11 Fig, 11 Ref.

Descriptors: *Ecological effects, *Water storage, *Runoff cycle, *Cycling nutrients, *Electric power production, Runoff, Seasonal variation, Estuaries, Salinity currents, Saline-freshwater interfaces, Tidal marshes, Continental shelf, Density currents.

The storage of spring and summer runoff to generate electric power may pose a serious threat to the freshwater supply required by estuaries, embayments, marshes, and continental shelves for the mixing and entrainment of nutrient-rich deep water into the surface layer. Along the northeastern United States and the eastern coast of Canada, the typical winter runoff of freshwater is small, but the spring and summer freshwater runoff into the estuaries is much larger. Reducing the flow of freshwater during spring and summer and increasing it during winter alters the seasonal composition of the water in the surface layer and the seasonal strength of the density current. Studies of salinity in the south side of Cabot Strait before regulation commenced, and in the 1970's after runoff regulation showed that drastic increases in salinity occurred after regulation and much of the cyclic variation in salinity had disappeared. If the trend continues, the cyclic variation will be reversed, summer and winter temperatures will probably increase and the strength of the density current may decline to the point of disappearance. Reductions in the transport of salt water will be accompanied by a decrease in the influx of nutrients during the active season of the year. (Geiger-FRC)

Descriptors: *Rivers, *Water quality, *Monitoring, Automation, Data acquisition, Water management, Equipment, Data processing, *Severn-Trent Water Authority, England.

In the Severn-Trent Water Authority a selection of commercial monitors is used together with specialist in-house developed monitors to help give a comprehensive water quality picture. Monitoring statins are expected to fulfill the two roles of sounding an alarm in the event of a polution problem and gathering historical quality data at that site. The procedure used to minimize false call-outs is briefly reviewed. The automatic data acquisition system is described, including data logger operations, and data recovery. Sensor technology has not as yet developed sufficiently to enable an automatic monitoring system to measure determinands which are most desirable, or if this is possible, costs are frequently prohibitive, particularly if a number of stations are required. At present, monitoring stations frequently measure determinands which may hint at undesirable contaminatino, but do not allow this to be quantified or identified unequivocally. Current sensors and sampling systems have a significant failure rate; consequently a limited proportion of erroneous results should be expected and dealt with accordingly. (Baker-FRC)

AUTOMATIC COLLECTION AND TRANSMISSION OF DATA FOR THE FEDERAL WATERWAY AUTHORITY.
Bundesanstalt fuer Gewasserkunde, Coblenz (Germany, F.R.).
F. Gunneberg.
Water Science and Technology, Vol 13, No 11/12, p 657-662, 1981. 1 Fig, 1 Tab.

Descriptors: *Automation, *Data transmission, *Data acquisition, Water quality data, On-site data collections, Hydrologic data, Flood data, Water level, Rivers, Germany, Remote control, Computers.

The West German Federal Waterway Authority is installing remote control equipment at its gauging and water quality monitoring stations in order to save labor costs and provide instantaneous access to water level data for flood prediction and pollution monitoring. Transmission is via the authority's own telephone lines. On-site storage of data for several days is provided in case of service interruption. Check channels are provided. Analog data from temperature, conductivity, acidity, and other sensors are transformed by an analog-digital converter, whereas water level data are obtained in digital form by coupling an optical encoder to the standard gauging facility. A quartz clock controlled microprocessor calls up gauging data every full minute, averages the data every 15 minutes, and stores the value in solid state memory. This procedure smooths the ripple caused by passing ships. Up to 22 sensors can be connected to one field station. The microprocessor is restarted every

LIBRARY U. OF I.- URBANA-CHAMPAIGN

day at midnight in order to protect against program execution breakdown due to power failures and the like. Maintenance personnel visiting the field station can plug in a liquid crystal display to read out the last values registered and the clock setting. Additional facilities are provided on regulated rivers. (Carroll-FRC)

DATA ACQUISITION FOR RIVER MANAGEMENT,
Thames Water Authority, Berkshire (England).
C. A. Hanson.
Water Science and Technology, Vol 13, No 11/12, p 687-692, 1981. 2 Ref.

Descriptors: *Water management, *Data acquisition, Computers, Monitoring, Automation, Rivers, *Thames River, River Lea, Catchment areas, *River systems, River management.

The requirements for data and information to manage and control a river system go beyond those for single process control. These requirements are discussed along with the philosophy of operation for the Thames Water data acquisition and control system for river management. This system has been operational since 1979. The system covers the catchments of the freshwater Thames above Teddington Lock and the River Lea, a major catchment which discharges directly to the tidal Thames and whose lower reaches pass through the outer conurbation of north east London. Both rivers have a navigational function. One of the additional requirements in river management beyond water supply and sewage treatment functions is for continuous time-series data as a prerequisite of system understanding before any meaningful control objectives can be established. Catchment data is also required to make projections for planning purposes. In river management data acquisition must be commenced in anticipation of problems to be met years ahead, and the quality of the data should assume decreasing margins of error and improving modelling techniques able to take advantage of the data quality. The first stage of the Thames Water data acquisition system consisted of a radio communications network, a computer control system and 67 field stations. Most of the difficulties encountered in commissioning the system revolved around the computer. At present attempts are underway to integrate the system of data from a precipitation radar station into the overall scheme. (Baker-FRC)

ELECTROMAGNETIC MEASUREMENTS OF TIDAL TRANSPORTS IN ESTUARIES,
Louisiana State Univ., Baton Rouge. Center for Wetland Resources.
E. M. Swenson.
Estuaries, Vol 4, No 3, p 161-166, 1981. 7 Fig, 17 Ref.

Descriptors: *Estuarine environment, *Tidal rivers, Electromagnetic waves, *Tidal range, *Measuring instruments, Monitoring, Flow, Flow measurement, Tidal flow.

An electromagnetic method for monitoring tidal flow, inexpensive and relatively maintenance free after deployment, is presented. This provides a possible alternative transport measurement system for understanding tidal transports. Comparison of the electric potential signal to transports determined from current meter records is used to calibrate the system. The method depends on the measurement of the electric potential produced across a tidal channel by tidal currents. The induced potential is proportional to the vector cross product of the magnetic field of the earth and the water velocity. A volume flow of 100 cubic meters per second will induce a potential near 1 mV. Examples are given of measurements taken at Great Bay, New Hampshire and Lake Pontchartrain, Louisiana. These examples illustrate the observation that the method is capable of yielding volume flow measurements with an uncertainty of about 15%. The method does have some limitations due to salinity and temperature changes, calibration drift, and lack of definition of the spatial characteristics of the flow. (Baker-FRC)

ICHTHYOPLANKTON SAMPLERS FOR SIMULTANEOUS REPLICATE SAMPLES AT SURFACE AND BOTTOM,
North Carolina State Univ. at Raleign. Dept. of Zoology.
R. G. Hodson, C. R. Bennett, and R. J. Monroe.
Estuaries, Vol 4, No 3, p 176-184, 1981. 3 Fig, 4 Tab, 9 Ref.

Descriptors: *Sampling, *Estuarine environment, *Plankton, Fish, Biomass, *Measuring instruments, Bottom sampling, Sampling devices.

The construction and use of some new and modified ichthyoplankton sampling devices are described. These devices can be operated from small, relatively fast boats in shallow estuarine waters using nets up to 1 meter in diameter. The gear uses one meter diameter nets on square and rectangular frames and provides simultaneous surface and bottom samples. The equipment provides quantitative and qualitative ichthyoplankton samples from shallow estuarine waters 1 to 12 meters deep. Filtration performance in relation to clogging of 505 micron mesh nets averaged 97% and 103% for the surface and bottom nets respectively. These high filtration rates were attributed to the design of the net frames, which apparently act as mouth reducing cones. Catch data for several species from the side-by-side and separated rigs were analyzed with a nested model of analysis of variance. No systematic error was noted to be inherent in the design of the two samplers, which precluded direct comparison of surface and bottom samples taken with them. (Baker-FRC)

MEASUREMENT OF AIR IN FLOWING WATER,
Washington State Univ., Pullman. Dept. of Civil and Environmental Engineering.
A. F. Babb, and H. C. Aus.
Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 107, No HY12, p 1615-1630, December, 1981. 16 Fig, 6 Ref.

Descriptors: *Bubbles, *Air entrainment, *Flow characteristics, Anemometers, Hydraulics, Water flow, Spillways, Flow velocity, Hot-film anemometer, Duration factor, Hydraulic engineering.

Air void fraction and bubble size were measured by the hot-film anemometer method, modified by a gamma-ray attenuation technique for calibrating the duration factor for the hot-film procedure. The duration factor, a function of velocity, varied from 1.5 msec for a velocity of 0.5 m per sec to 0.5 msec for 3.5 m per sec. Errors produced by computer identification of a nonexistent bubble and failure to detect the end of the bubbles were minimized by concurrent display of the anemometer signal and a computer signal indicating whether air or water was being detected. Minimum detectable bubble size was a function of the duration factor, and in turn, of velocity. Void ratio and bubble size were studied in a stable hydraulic jump maintained at a Froude number of 6. Larger bubbles, about 10 mm, were located near the upstream end of the jump. Larger bubbles were easily broken by turbulence, shear, and buoyancy. (Cassar-FRC)

A PROBE METHOD FOR SOIL WATER SAMPLING AND SUBSURFACE MEASUREMENTS,
Alaska Univ., Fairbanks. Geophysical Inst.
W. D. Harrison, and T. E. Osterkamp.
Water Resources Research, Vol 17, No 6, p 1731-1736, December, 1981. 5 Fig, 16 Ref.

Descriptors: *Soil water, *Sampling, *Sediment sampler, Interstitial water, Permafrost, Sea ice, *Beaufort Sea Shelf, Alaska, Hydraulic conductivity, Water pressure, Temperature, Measurements, Water sampling.

An apparatus for obtaining interstitial soil water samples was applied in a study of sediments under the sea ice of the Beaufort Sea Shelf, Alaska. The portable, inexpensive sampler consists of a probe, metal shield, porous metal filter, and a check valve connected to the surface by plastic tubing inside a drill rod. It is designed for use in the saturated zone and works best in coarse-grained sediments difficult to sample by other methods. The water sample is removed with a bailer inside the tubing. It is not necessary to remove the probe between samples at different depths in the same hole. The apparatus may also be used to measure hydraulic conductivity, temperature, and water pressure. Special problems encountered in working with the permafrost sediments were: the interstitial soil water was partly frozen and only the liquid phase was collected, freezing in the tubing occurred occasionally, and bailers and sometimes tubing had to be warmed electrically before using. A NEW METHOD FOR SAMPLING SNOW MELT AND RAINFALL IN FORESTS,
Northeastern Forest Experiment Station, Parsons, WV. Timber and Watershed Lab.
J. D. Helvey, and W. B. Fowler.
Water Resources Bulletin, Vol 16, No 5, p 938-940, October, 1980. 2 Fig, 7 Ref.

Descriptors: *Snowmelt, *Measuring instruments, Lysimeter, Rainfall, Precipitation, Snow, Forest soils, Forest watersheds, Remote sensing, *Automation.

A technique is described for automatically recording the rate of snow melt at remote sites. The method can also be used for estimating liquid precipitation at the soil surface. The advantages of the method include the fact that water input to the forest floor is sampled directly and corrections for interception are not required; that windeffects on moisture deposition are completely avoided; that the system operates unattended for long periods of time; that the system is versatile in that the number and size of catch pans can be changed according to expected point to point variability in melt rates, and the size of the buckets can be changed; and the system can be adapted to a telemetering system for data transfer. THE USE OF LANDSAT IMAGERY IN GROUND WATER EXPLORATION,
Arizona Univ., Tucson. Dept. of Mining and Geological Engineering.
K. E. Foster, R. A. Schowengerdt, and C. E. Glass.
Water Resources Bulleting, Vol 16, No 5, p 934-937, October, 1980. 3 Fig, 2 Tab, 17 Ref.

Descriptors: *Groundwater, *Remote sensing, *Landsat, Satellite technology, Water resources development, Water supply development, Water supply, *Arizona, Mapping, *Geohydrology.

A study was undertaken in 1978 to develop methods of exploring for water supplies based upon faulting detectable in satellite imagery. Northeastern Arizona was the site of the study. Control sites near Flagstaff and St. Johns were selected for more detailed investigation. The study was conducted in three phases. During Phase I lineaments ithin the entire study area were mapped using standard Landsat 1:250,000 scale, false color composites. Phase II, conducted simultaneously with Phase I, consisted of an inventory within the two study sites of well location, depth, land-surface altitude, yield, drawdown, specific capacity, and transmissivity. Four hydrologic parameters were chosen to correlate with lineament data: specific capacity, transmissivity, water temperature, and specific conductance. During Phase III a methodology was developed to correlate mapped lineaments with the hydrologic data. A well centered grid model was used in which the cumulative length of lineaments within a specified radial distance from each well was correlated with the four hydrologic parameters by use of linear regression. The correlations developed between lineament density and water data for the Flagstaff and Springerville well fields support the hypothesis that a relationship exists between regional geologic structure and well production. The study indicates that if there is a relationship between Landsat mapped lineaments and smaller fracturing in a given area, this two stage procedure can provide an efficient approach to groundwater exploration over large areas. SOIL CONSERVATION SERVICE RUNOFF CURVE NUMBER ESTIMATES FROM LANDSAT DATA,
Science and Education Administration, Athens, GA.
R. B. Slack, and R. Welch.
Water Resources Bulletin, Vol 16, No 5, p 887-893, October, 1980. 7 Fig, 5 Tab, 12 Ref.

Descriptors: *Remote sensing, *Runoff forecasting, Hydrology, *Watersheds, *Mapping, Topographic mapping, *Landsat, Computers, Erosion, Soil conservation.

The possibility of deriving Soil Conservation Service (SCS) curve numbers for large watersheds from Landsat digital data is discussed. A curve number is a quantitative descriptor of the land cover/soil complex and is commonly assigned based on information gained from field surveys and interpretations of aerial photographs. The current study took place over the Little River watershed near Tifton, Georgia, an area of about 125 square miles. Landsat data was used to generate a classification map of this area with four hydrologically important classes: agricultural vegetation, forest, wetland, and bare ground. Missing soil data was interpolated from the vegetation patterns of the classification map. About half of the needed data was available from the Landsat experiment. A modification of the SCS curve table number was developed and used to assign each pixel to a category. The average curve number for each of six subwatersheds and for the entire watershed was then computed and compared with SCS values for the same areas. Agreement was to within two curve number units. The multitemporal aspect of Landsat permits the selection of image data at periods of the year when land cover and runoff considerations are critical to hydrologic studies. The digital format of Landsat data is compatible with the input requirements of hydrologic models. It appears feasible to combine in a data base the CN's for pixel or grid cell sized units with information on soils, precipitation, slope, aspect, vegetation, and land use. Such an approach would permit refinement of hydrologic models. (Baker-FRC)

ANALYSIS AND PREDICTION OF WATER MOVEMENTS AND WATER QUALITY IN A SHALLOW RIVER IMPOUNDMENT. APPLICATION TO MISSISSIPPI RIVER POOL NO 2,
A. C. Demetracopoulos.
PhD Thesis, June, 1981. 280 p, 70 Fig, 7 Tab, 190 Ref, 5 Append. University Microfilms International, Ann Arbor, MI; Order No GAX81-25950.

Descriptors: *Water quality, *Flow system, *Hydrologic aspects, *Model studies, Dissolved oxygen, Water circulation, Ponds, Mass transfer, *Impoundments, River systems, *Mississippi River, Water movement, Temporal variation, Spatial variation, Flow analysis.

The physical processes governing water circulation and hydrologic mass transport, as well as some of the biochemical processes determining the oxygen characteristics of shallow river impoundments are studied. Flow analysis is performed for an interconnected system of channels and for quasi-steady state conditions. The bulk flow is examined and interest is focused on the dynamic behavior of the flow. The response time of the aquatic system to changing wind conditions is examined in a simplified unsteady flow analysis. The study is extended to the water quality of shallow run-of-the-river impoundments. The main quality parameters are dissolved oxygen and algal biomass, The formulation and incorporation of the source and sink terms are addressed in the study. The validity of the combined hydrodynamic/transport/water quality model is checked against field measurements obtained in Pool 2 of the Mississippi River. The results are reasonable and show the significance of several interacting processes on dissolved materials and in particular dissolved oxygen very clearly. The model predicts concentrations of a dissolved conservative tracer or material, of dissolved oxygen, chlorophyll-a and water temperature. It is particularly suitable for low flow summer conditions when wind effects become significant or dominant and water quality exhibits strong temporal and spatial variations. (Sinha-OEIS)

WATER QUALITY MONITORING SYSTEM IN NIEDERSACHSEN - APPLICATION OF AUTOMATIC STATIONS FOR CONTROL AND MONITORING OF WATER QUALITY,
Niedersachsisches Wasseruntersuchungsamt, Hildesheim (Germany, F.R.).
V. Plate.
Water Science and Technology, Vol 13, No 11/12, p 671-676, 1981. 1 Fig, 1 Ref.

Descriptors: *Water quality, *Monitoring, Flood protection, *Automation, *Data transmission, Data acquisition, *Germany, Lower Saxony, Networks, Costs, Water level, Water resources management.

A network of 36 automatic monitoring stations is being developed in Lower Saxony in accordance with the reorganization of the water quality surveillance system now being undertaken. This network will be connected with a surveillance center in Hildesheim. The monitoring system will offer continuous observation of the water quality, allow for early recognition and announcement of deterioration or dangerous situations, and provide basic documentation for the purposes of studying water resources policies and management. The system will be completed by 1985. Principles, tasks and aims of the surveillance system as well as technical equipment of the monitoring stations, methods of data acquisition and tramsmission and the organization of the surveillance center in Hildesheim are described. Some timing and cost information is presented. About 30 of the most important water level gauge stations will be equipped with instrumentation appropriate for digital acquisition of water level measurement values and remote data transmission, especially for the purpose of flood protection. MANUAL GROUNDWATER SAMPLING DEVICE (VORRICHTUNG ZUR MANUELLEN WASSERPROBENENTNAHME AUS GRUNDWASSERMESSSTELLEN),
Forschungszentrum Wassertechnik (German,D.R.).
V. Peukert.
Wasserwirtschaft-Wassertechnik, Vol 31, No 10, p 336, 1981, ! Fig. (No English summary).

Descriptors: *Groundwater, *Sampling, *Equipment, Automation, *Water quality, Water sampling, Dissolved oxygen, Germany.

The standard technique for groundwater quality analysis in the German Decocratic Republic requires that the collecting tube be flushed before the sample is collected, a procedure which was difficult to accomplish with existing sampling devices. A new device was developed which permits a representative groundwater sample to be collected, based on a vacuum principle. This principle requires a difference of less than 9 m in height between the groundwater level and the sampler. A converted automatic air pump creates a vacuum, maintained by means of a check valve, in the sampling line. Water is drawn up through the collecting tube. Once the collection vessel is filled, ambient pressure is restored by opening a three-way stopcock, and the water collected is either placed in the sampling bottle or discarded. A water volume at least equal to the volume of tubing between the water level and the filter area is pumped out and discarded. Then the sample is drawn off from just above the filter. Introduction of oxygen to the sample is prevented by keeping the system closed and filling the reservoir completely during sampling. The desired sample water volume is carefully pipetted from the reservoir into a sample bottle. (Carroll-FRC)

UTILIZATION OF DATA FROM AUTOMATIC WATER QUALITY MONITORING STATIONS IN FINLAND,
National Board of Waters, Helsinki (Finland). Water Research Inst.
T. Kohonen.
Water Science and Technology, Vol 13, No 11/12, p 631-637, 1981. 3 Fig, 1 Tab, 7 Ref.

Descriptors: *Water quality, *Monitoring, *Automation, Computers, Data acquisition, Water management, *Finland, Networks, Turbidity, Dissolved oxygen, Rivers, Hydrogen ion concentration, Chloride, Kymyoki River, Kokemaenjokia, *Data transmission.

The Kymijoki River and Kokemaenjoki River monitoring network comprises five land-based river stations and a central commputing unit consisting of a PDP 11/35 computer located at the Helsinki office of the National Board of Waters. The system began service in September of 1977. Data transfer from the station occurs twice daily via leased public telephone lines and is initiated by the computer. Data can also be requested manually from a control terminal if the need arises. Every monitoring station measures temperature, pH, conductivity, dissolved oxygen, turbidity, and chloride level at five stations and redox potential at two of the stations. In seven sstations the measuring cham-

LIBRARY U. OF I.- URBANA-CHAMPAIGN

ber also houses the built-in ultrasonic transducers for cleaning the sensors hourly, together with the drive motors needed for daily calibration and cleaning cycles. The quantity of the data gathered allows the use of statistical procedures for estimating the optimal sampling frequencies. (Baker-FRC)

RECENT DEVELOPMENTS IN AND APPLICATION OF AUTOMATION AND MONITORING IN WATER MANGEMENT,
Bundesgesundheitsamt, Berlin (Germany, F.R.). Inst. fuer Wasser-, Boden-, und Lufthygiene.
R. Leschber.
Water Science and Technology, Vol 13, No 11/12, p 715-719, 1981.

Descriptors: *Water management, *Reviews, *Monitoring, Automation, Water supply, *Water quality, Water quality control.

This communication briefly reviews the main subjects presented at the Congress and Exhibition 'Wasser Berlin '81' and the essential new ideas and results of research. The range of subjects covered at the conference included general reports on the present and future role of automation and related fields in water management as well as papers which dealt with telemetry and micro-processors. Monitoring of surface waters and other drinking water sources made up another group of subjects. The bulk of papers pertained to the subjects of water treatment and supply. The two most advanced systems operating in Switzerland were described, one of which operates without any technical staff and the other where staff can rely on the most conemporary aids of data processing. Data flow, data storage, and data retrieval in the form of periodic reports were described. In the fields of water treatment the major subjects were dosage of chemicals and monitoring of the success of the individual stages of treatment. Automation of sequences of procedures or complex methods of treatment was considered. The great advantage of using a computer with reserve capacity for specific raw water treatment was considered. Water supply was covered in papers dealing with general problems of the operation of municipal networks and a number of specific subjects. The various applications of servosystems for the operation of pumps and valves were described. (Baker-FRC)

STORM SEWER FLOW COMPUTATIONS,
Lanchester Polytechnic, Coventry (England). Dept. of Civil Engineering.
K. Sivaloganathan.
Proceedings of the Institution of Civil Engineers, Part 2: Research and Theory, Vol 71, No 2, p 513-522, June, 1981. 8 Fig, 1 Tab, 12 Ref.

Descriptors: *Sewer systems, Lateral sewers, *Pipe flow, *Storm sewers, Hydraulics, *Flow characteristics, Hydrographs.

A new technique for dealing with storm sewer flows involving concentrated lateral inflows at junctions is described. Using St. Venant equations, each concentrated lateral inflow is replaced by a triangularly distributed lateral inflow over the adjoining few distance steps. The diffusing and the Lax- Wendroff methods were most suitable for solving the St. Venant equations with this technique. The implicit method of Strelkoff may be used if the equivalent triangular distribution of each concentrated lateral inflow is not done over too small a distance. Methods unsuitable for this technique were the rectangular grid broken characteristic scheme and the leap frog method. Depth hydrographs prepared from experimental and computed data were in good agreement. (Cassar-FRC)

THE DEVELOPMENT OF A VIABLE METHOD OF STREAM FLOW MEASUREMENT USING THE INTEGRATING FLOAT TECHNIQUE,
Lancaster Univ., Bailrigg (England).
D. M. Sargent.
Proceedings of the Institution of Civil Engineers, Part 2: Research and Theory, Vol 71, No 1, p 1-15, March, 1981. 10 Fig, 2 Tab, 8 Ref.

Descriptors: *Flow measurement, *Streamflow, *Bubbles, Integrating float method, Photography.

The integrating float method for measuring streamflow was modified by using air bubbles as rising floats. This method, first suggested a century ago, has never been practical because the buoyant floats in the stream were difficult to locate. A length of pipe was installed in a straight line across the river bottom. Air was forced through nozzles placed at intervals along the pipe to produce a line of rising air bubbles. Photographic equipment was set up on the bank to record the position of the air bubble line. Streamflow values obtained using the integrating float method in a medium-sized river were within -6 to +10% (average 1.3%) of streamflows measured by a weir. Errors were greatest at low and high flow. (Cassar-FRC)

REMOTE SENSING OF ATMOSPHERIC WATER CONTENT FROM SATELLITE MICROWAVE RADIOMETER (SAMIR) ON BHASKARA,
Indian Space Research Organization, Ahmedabad. Space Applications Centre.
P. C. Pandley, B. S. Gohil, and A. K. Sharma.
Mausam, Vol 32, No 1, p 17-22, January, 1981. 5 Fig, 2 Tab, 21 Ref.

Descriptors: *Remote sensing, *Atmospheric water, *Meteorological data collection, Water vapor, Microwaves, Radiosondes, *India, Bay of Bengal, Arabian Sea, Satellite technology, Radiometry, *Bhaskara satellite.

Integrated abundances of water vapor and liquid water over oceans were determined from data obtained from the Indian satellite Bhaskara during its June 27, 28, and 29, 1979, orbits. Aboard the satellite is a microwave radiometer (SAMIR) with 19.35 GHz and 22.235 GHz channels. Values of water vapor and liquid water content, respectively, were: June 27 over the Arabian Sea, 4.0 g per sq cm and 0.5-0.7 kg per sq m; June 28 over the Bay of Bengal, 4.4-6.0 g per sq cm and 0.8-2.1 kg per sq m; and June 29, a tropical depression over the Bay of Bengal, 3.6-4.7 g per sq cm and 1.7-1.9 kg per sq m. Although no accurate data were available for comparison, the findings were in general agreement with mean monthly precipitable water radiosonde data from coastal stations and from APT pictures. (Cassar-FRC)

COLLAPSIBLE-BAG SUSPENDED-SEDIMENT SAMPLER,
Geological Survey, Lakewood, CO.
H. H. Stevens, Jr., G. A. Lutz, and D. W. Hubbell.
Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 106, No HY4, p 608-611, April, 1980. 2 Fig, 5 Ref.

Descriptors: Water sampling, *Suspended sediments, Rivers, Estuaries, Measuring instruments, *Sediment sampler.

The U. S. Federal Interagency Sedimentation Committee has developed special sampling techniques and equipment to help ensure the collection of meaningful samples of the suspended-sediment load in rivers and estuaries. This paper describes a collapsible-bag sampler that is based on somewhat different operating principles than conventional U.S.-series samplers, but which has similar sampling characteristics and is used in the same manner as those samplers. This collapsible bag sampler facilitates the collection of samples from large rivers and estuaries because it permits the continuous collection of representative depth-integrated samples of water-sediment mixture in all water depths and velocity distributions and the convenient and quick collection of large volume samples. In addition, the maximum depth capacity of the sampler can be readily changed by altering the internal diameter of the nozzle or the volume of the sample bag. The nozzle of the container can easily be fitted with an off-on valve to permit the sampler to be used as a point-integrating sampler. The sampler is easy to use and to maintain, even in salt water. Various potential improvements in the sampler are also identified. (Carroll-FRC)

WATERSHEDS AS THE BASIC ECOSYSTEMS: THIS CONCEPTUAL FRAMEWORK PROVIDES A BASIS FOR A NATURAL CLASSIFICATION SYSTEM,
Corvallis Environmental Research Lab., OR.
F. B. Lotspeich.
Water Resources Bulletin, Vol 16, No 4, p 581-586, August, 1980. 1 Fig, 27 Ref.

Descriptors: *Watersheds, *Ecosystems, *Stream classification, Classification, Climate, Geology, Soil, Vegetation.

A classification scheme for watersheds, based on the ecosystem concept, is outlined. Climate and geology are selected as the state factors. These two factors interact to produce a land form and in turn an ecosystem. Climate is considered the master factor, having overwhelming influence on all ecosystem features. Possible classes of climate can be based on size, the concept of equivalent latitude, or the isophane concept (lines of equal biological activity as a function of temperature, which is in turn a function of latitude and elevation). Geology classifications may consider bedrock. Transactional factors are soil and vegetation, which interact with climatic and geologic factors to form a variety of tesseras. The stream, at the bottom of the scale, is passive and does not interact with the higher factors in the ecosystem. The stream is a result of interactions of all the forces on the two higher levels. DECISIONS UNDER VIOLATION OF REGRESSION NORMALITY,
Arizona Univ., Tucson. Dept. of Systems and Industrial Engineering.
E. Castano, L. Duckstein, and J. Weber.
Journal of the Water Resources Planning and Management Division, Proceedings of the American Society of Civil Engineers, Vol 107, No WR2, p 549-561, October, 1981. 1 Tab, 5 Fig, 35 Ref.

Descriptors: *Mathematical models, *Statistical analysis, *Management planning, Decision making, *Regression analysis, *Hydrology, Prediction, Engineering, Monte Carlo methods, Simulation, Distribution.

The accuracy of hydrologic predictions based on regression analysis under the incorrect assumption of normality is investigated. Monte carlo simulation is used to investigate the small sample behavior of the estimated regression coefficients, estimated variances, and predicted values of the dependent variable when the errors are not normally distributed. The distributions simulated are lognormal, Pearson, and LogPearson with varying degrees of skew. The estimated values of the regression coefficients are not appreciably affected by skew of the error distribution. Decisions based on both the mean and variance are less robust to nonnormality than decisions based only on the mean. For example, whenever hydrologic decisions are based on a percentile, as in T-year floods, or on a confidence interval statement in regression analysis, as in flood plain zoning, standard deviations are involved, so that results may be sensitive to violation of the normality assumption. VERTICAL ROUND BUOYANT JET IN SHALLOW WATER,
Delaware Univ., Newark. Dept. of Civil Engineering.
J. H. W. Lee, and G. H. Jirka.
Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 107,

No HY12, p 1651-1675, December, 1981. 10 Fig, 2 Tab, 23 Ref.

Descriptors: *Cooling water, *Mixing, *Thermal pollution, Dilution, Powerplants, Tracers, Dyes, Shallow water, Jets, Water pollution control, Buoyancy, Fate of pollutants, Hydraulics, Flow characteristics, Turbulent flow.

The stability and mixing characteristics of a round turbulent buoyant jet discharging vertically into a stagnant water body of large horizontal extent were investigated analytically and experimentally to determine the aquatic impact of thermal effluents. In the case of a stable discharge configuration, four flow regimes can be distinguishd: (1) initial buoyant jet region, where the discharge mixes with the ambient fluid by turbulent entrainment, (2) surface impingement region, where the buoyant mixed flow is turned into a radially outward moving supercritical flow, (3) radial internal hydraulic jump region, transferring the flow into a subcritical region downstream with loss of energy, and (4) stratified counterflow region, with negligible entrainment across the surface. These 4 regions are analyzed separately and the solutions combined to predict the stability criteria. A laboratory half jet and dye were used to observe flows under different conditions. Jet diameters varied from 1.0 to 0.25 inches; discharge velocities, 0.82 to 30.0 ft per sec; discharge excess temperatures, 21.4 to 34.8 F; initial ambient temperatures, 70.2 to 79.1 F; discharge flows, 0.31 to 3.20 gal per min; Froude numbers, 8.0 to 583.4; and Reynolds numbers, 6800 to 62,500. Stability or nonstability and near field dilution were noted. This study indicates that shallow site conditions limit the dilution possible with single port discharges. Alternative designs include moving the outfall to greater depths or using a multiport diffuser. (Cassar-FRC)

MAPS SHOWING GROUND-WATER CONDITIONS IN THE BILL WILLIAMS AREA, MOHAVE, YAVAPAI, AND YUMA COUNTIES, ARIZONA--1980,
Geological Survey, Tucson, AZ. Water Resources Div.
H. W. Sanger, and G. R. Littin.
Geological Survey Open-File Report 82-87 (WRI), November, 1981. 2 Sheets, 16 Ref.

Descriptors: *Maps, *Groundwater, *Aquifer characteristics, *Water quality, Water level, Wells, Springs, Specific conductivity, Fluoride, *Arizona, Mohave County, Yavapai County, Yuma County, Bill Williams River.

The Bill Williams area includes about 3,200 square miles in west-central Arizona. Most water used is from ground water, although a small amount of surface water also may be diverted. About 18,000 acre-feet of ground water was withdrawn in 1979. The main water-bearing unit is the basin-fill deposits, which consist of boulder to pebble conglomerate and interbedded coarse- to fine-grained sandstone, siltstone, mudstone, and in places rhyolitic and basaltic tuff. Depth to water, altitude of the water level, well depth, and specific conductance and fluoride concentration are shown on the 1:125,000-scale map of the area. (USGS)

FLOOD AND RELATED DEBRIS FLOW HAZARDS MAP, LAS VEGAS SE QUADRANGLE,
Geological Survey, Carson City, NV. Water Resources Div.
T. Katzer.
Available from Nevada Bureau of Mines and Geology, Univ. of Nevada, Reno, Nevada 89557, Price: $2.50. Nevada Bureau of Mines and Geology Map 3A1, 1981. 1 Sheet.

Descriptors: *Maps, *Floods, *Detritus, *Hazards, Flood peak, Flood plains, Flood flow, Erosion, Deposition, *Nevada, *Las Vegas SE quadrangle.

This map shows flood and debris hazards on the Las Vegas SE quadrangle, Nevada. Estimates of the 100-year flood peak were made and the corresponding flood plains were outlined on the map for the principal drainages in the area. Degrees of hazard were assigned to the entire quadrangle on the basis of floodflows and potential debris movement. (USGS)

THICKNESS, PERCENT SAND, AND CONFIGURATION OF SHALLOW HYDROGEOLOGIC UNITS IN THE POWDER RIVER BASIN, MONTANA AND WYOMING,
Geological Survey, Billings, MT. Water Resources Div.
B. D. Lewis, and W. R. Hotchkiss.
Available from Western Distr. Branch USGS, Box 25286 Denver, CO 80225, Price: $12.50. Geological Survey Miscellaneous Investigations Map I-1317, 1981. 6 Sheets, 23 Ref.

Descriptors: *Maps, *Geohydrology, *Geohydrologic units, *Aquifer characteristics, Hydrologic data, Geology, Geological surveys, *Montana, *Wyoming, Powder River basin.

The shallow hydrogeologic system is composed of five distinct units, bounded at its base by the regionally widespread and relatively impermeable Bearpaw Shale. The units, which were in age from Late Cretaceous to Holocene, are in ascending order the Fox Hills-lower Hell Creek aquifer, upper Hell Creek confining layer, Tullock aquifer, Lebo confining layer, and Tongue River-Wasatch aquifer. Shallow hydrogeologic units mapped in the Powder River basin of Montana and Wyoming are of marine and continental origin. The Fox Hills Sandstone is a marine deposit with all overlying units representing continental conditions. Thick and extensive coal deposits are present in the Tongue River Member of the Fort Union Formation and the Wasatch Formation. Geologic and hydrogeologic data were used to separate the various units into a system of alternating aquifers anf confining layers. Physical characteristics used to describe the units were thickness, percent sand, and configuration of the base of each hydrogeologic unit. (USGS)
W82-04501

DISSOLVED-SOLIDS CONCENTRATIONS OF GROUND WATER IN THE SACRAMENTO VALLEY, CALIFORNIA,
Geological Survey, Sacramento, CA. Water Resources Div.
R. P. Fogelman.
Available from Western Distr. Branch USGS, Box 25286 Denver, CO 80225, Price: $3.00. Geological Survey Hydrologic Investigations Atlas HA-645, 1982. 1 Sheet, 1 Tab, 14 Ref.

Descriptors: *Maps, *Dissolved solids, *Groundwater, *Water quality, Wells, Irrigation, Domestic water, Water analysis, Chemical analysis, Geohydrology, *California, *Sacramento Valley.

The general quality of the ground water in the Sacramento Valley, Calif., in terms of dissolved-solids concentration is considered good for irrigation, domestic, and most other uses. This map shows the distribution of dissolved-solids concentrations and is based on about 1,330 chemical analyses collected from about 900 wells between 1974 and 1978. On the west side of the valley some of the smaller streams contribute water of higher dissolved-solids concentrations to the ground water. The sources of these waters are thought to be the upper Cretaceous Chico Formation or marine deposits of Early Cretaceous age that are exposed in the Coast Ranges. (USGS)

WATER RESOURCES DATA FOR ARKANSAS, WATER YEAR 1980.
Geological Survey, Little Rock, AR. Water Resources Div.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-190380, Price codes: A25 in paper copy, A01 in microfiche. Geological Survey Water-Data Report AR-80-1, 1981. 585 p, 5 Fig, 3 Tab.

Descriptors: *Hydrologic data, *Surface water, *Groundwater, *Water quality, Gaging stations, Streamflow, Flow rates, Sediment transport, Water analysis, Water temperature, Chemical analysis, Lakes, Reservoirs, Wells, Water level, Data collections, Sites, *Arkansas.

Water resources data for the 1980 water year for Arkansas consist of records of stage, discharge, and water quality of streams; and stage, contents, and water quality of lakes and reservoirs. This report contains discharge records for 60 gaging stations; stage and contents for four lakes and reservoirs; water quality for 152 stations, 69 partial-record flow stations, and eight lakes; and water levels for 79 observation wells. Also included are 116 crest-stage partial-record stations. Additional water data were collected at various sites, not part of the systematic data-collection program, and are published as miscellaneous measurements. These data represent that part of the National Water Data System operated by the U.S. Geological Survey and cooperating State and Federal agencies in Arkansas. (USGS)
W82-04503

HYDROLOGIC RECONNAISSANCE OF THE BELUGA, PETERS CREEK, AND HEALY COAL AREAS, ALASKA,
Geological Survey, Anchorage, AK. Water Resources Div.
D. R. Scully, A. P. Krumhardt, and D. R. Kernodle.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-168402, Price codes: A05 in paper copy, A01 in microfiche. Geological Survey Water-Resources Investigations 81-56, 1981. 71 p, 37 Fig, 17 Tab, 31 Ref.

Descriptors: *Surface water, *Water quality, *Hydrologic data, *Coal mines, Streams, Flow characteristics, *Alaska, Beluga coal area, Peters Creek coal area, Healy coal area.

The Beluga, Peters Creek, and Healy coal areas in Alaska were studied during 1975-1978, with major emphasis on surface-water hydrology and water quality. In the Beluga coal area, mean annual discharge is estimated to range from 2.2 to 3.4 cubic feet per second per square mile of drainage area. The 7-day low flow with a 10-year recurrence interval is estimated to be 0.3 to 0.6 cubic feet per second per square mile. The surface waters are calcium bicarbonate type; have low concentrations of nutrients; and, at times, may contain dissolved iron and manganese in concentrations in excess of U.S. Environmental Protection Agency recommended limits. The pooled diversity index of the benthic invertebrate community ranges from 2.93 to 4.06. No ground-water wells have been drilled in the potential mining areas. Water quality of streams in the Peters Creek coal area is similar to that of the streams in the Beluga coal area. No attempt is made to define streamflow characteristics in the Peters Creek coal area due to poor correlations with nearby gaging stations. In the Healy coal area, streamflow characteristics are dissimilar between the two major basins studied. Lig-

LIBRARY U. OF I.- URBANA-CHAMPAIGN

nite Creek is estimated to have less yield than Healy Creek. Studied tributaries of Healy and Lignite Creeks contain waters with a dissolved solids range of 111 to 636 milligrams per liter and have calcium and bicarbonate or magnesium and bicarbonate as principal ions. Iron and manganese concentrations are high at some times of the year. The concentrations of sodium and chloride increases significantly in the lower reaches of Lignite Creek. (USGS)
W82-04504

POTENTIOMETRIC SURFACE OF THE FLORIDAN AQUIFER IN CENTRAL SUMTER COUNTY, FLORIDA, MAY 1981,
Geological Survey, Orlando, FL. Water Resources Div.
A. S. Navoy.
Available from OFSS, USGS Box 25425, Fed. Ctr. Denver, CO 80225. Paper copy $2.50, Microfiche $0.50. Geological Survey Open-File Report 81-1198, 1981. 1 Sheet.

Descriptors: *Potentiometric level, *Groundwater, *Maps, *Aquifers, Water table, Wells, Water level fluctuations, Pumping, Geohydrology, *Florida, Sumter County.

This map presents the potentiometric surface of the Floridan aquifer in central Sumter County, Fla., for May 1981. The Floridan aquifer is the principal source of potable water in the area. The focus of the map is the potentiometric surface in the Jumper Creek Canal area for the low water-level period. Water-level measurements were made on approximately 60 wells. The potentiometric surface ranged in altitude from more than 90 feet in the southeast part of the county to less than 35 feet northwest of Lake Panasoffkee in the west central area. (USGS)
W82-04507

WATER-RESOURCES INVESTIGATIONS OF THE U.S. GEOLOGICAL SURVEY IN KANSAS--FISCAL YEAR 1979 AND 1980,
Geological Survey, Lawrence, KS. Water Resources Div.
H. E. McGovern, and L. J. Combs.
Geological Survey Open-File Report 81-348 (WRI), March, 1981. 107 p, 9 Fig, 5 Tab.

Descriptors: *Available water, *Water quality, *Groundwater, *Surface water, Water resources development, Water management, Aquifers, Selective withdrawal, Irrigation, Water use, Water supply, Streamflow, Runoff, Sediment transport, Flood frequency, Urbanization, Data collections, Publications, *Kansas, *Projects.

Activities of the U.S. Geological Survey in Kansas include the systematic collection and analysis of data to describe the framework of hydrologic systems, assess the water resources, define existing or potential problems in the quantity or quality of water, and provide information for optimum development and management of resources. Streamflow studies are made to determine availability of supplies and relations to rainfall runoff, urbanization, flood frequencies, and sediment-transport. Groundwater studies are made to determine the quantity of supplies available in aquifer systems, the effects of natural or artificial contamination, and the effects of withdrawals by irrigation, industrial, and municipal supplies. Water-quality studies are made to define physical, chemical, and biological characteristics in streams and principal aquifers, and to evaluate the chemical changes due to urbanization and surface mining. (USGS)
W82-04510

PROBABLE HIGH GROUND-WATER LEVELS ON CAPE COD, MASSACHUSETTS,
Geological Survey, Boston, MA. Water Resources Div.
M. H. Frimpter.
Geological Survey Open-File Report 80-1008 (WRI), 1980. 20 p, 5 Fig, 4 Plates, 10 Tab, 7 Ref.

Descriptors: *Groundwater, *Water table, *Observation wells, *Water level fluctuations, Sites, Maps, Estimating, Massachusetts, *Cape Cod.

Water-level records from 146 short-term (1 year) observation wells and 13 long-term (16-28 years) observation wells were used to estimate the probable high ground-water level that could occur at any site on Cape Cod. The estimation was based on correlation of a single water-level measurement from a test site with water-level records of the nine index wells. Maps showing areas of Cape Cod represented by the nine index wells and showing five ranges of water-level fluctuation are used in conjunction with tables of water-level adjustments to make the estimates. PRELIMINARY DATA FROM ARBUCKLE TEST WELLS, MIAMI, DOUGLAS, SALINE, AND LABETTE COUNTIES, KANSAS,
Geological Survey, Lawrence, KS. Water Resources Div.
T. Gogel.
Available from OFSS, USGS Box 25425, Fed. Ctr. Denver, CO 80225. Paper copy $20.00, Microfiche $3.50. Geological Survey Open-File Report 81-1112, 1981. 155 p, 54 Fig, 16 Tab, 3 Ref, 2 Append.

Descriptors: *Hydrologic data, *Aquifer characteristics, *Structural geology, *Cores, Test wells, Hydraulics, Water quality, Water analysis, Hydraulic conductivity, Logging(Recording), Geochemistry, *Kansas, Arbuckle Group, Miami County, Douglas County, Saline County, Labette County.

Preliminary data are presented for test wells in Kansas that were completed in Cambrian and Ordovician rocks of the Arbuckle Group in late 1979 and early 1980. Included in the report are hole history, electrical logs, geology (sample descriptions and cores), hydrologic testing, and geochemistry. These wells were drilled to determine the regional hydrology of the Arbuckle Group and to investigate the hydraulic characteristics of the formation at site-specific areas. The test wells were drilled in Miami, Douglas, Saline, and Labette Counties, Kansas. Depths of the wells ranged from 1,816 feet in Labette County to 3,665 feet in Saline County. Results of core analyses from rocks in the Arbuckle Group are presented for vertical and horizontal permeability to air, porosity, fluid saturation, acoustic velocity, resistivity indices, and formation factor. Formation data from drill-stem tests are presented for use in calculating transmissivity, hydraulic conductivity, and hydraulic head. Analyses of water samples from the test wells are presented to indicate water quality in the aquifers. (USGS)
W82-04512

WATER-QUALITY DATA FOR SELECTED STATIONS IN THE EAST EVERGLADES, FLORIDA,
Geological Survey, Tallahassee, FL. Water Resources Div.
B. G. Waller.
Available from OFSS, USGS Box 25425, Fed. Ctr. Denver, CO 80225. Paper copy $10.75, Microfiche $3.50. Geological Survey Open-File Report 81-821, 1981. 77 p, 6 Fig, 37 Tab, 1 Ref.

Descriptors: *Water quality, *Data collections, *Surface water, *Groundwater, Canals, Marshes, Bottom sampling, Water analysis, Nutrients, Trace elements, Algae, *Florida, Dade County, *Everglades.

The results of water-quality samples collected from April 1978 through April 1980 from three canal stations, four marsh stations, and two ground-water stations within the East Everglades, Dade County, Florida, are tabulated in 37 tables. The major categories of parameters analyzed are field measurements, physical characteristics, macronutrients (carbon, nitrogen, and phosphorus), major ions, trace elements, and algae. Chemical data for bulk-precipitation stations within and adjacent to the East Everglades are also given. The parameters analyzed include macronutrients, major ions, and trace elements. The period of record for these stations is October 1977 through April 1980. Bottom material at the canal and marsh stations was collected twice during the investigation. These data include analyses for macronutrients, trace elements, and chlorinated-hydrocarbon insecticides. (USGS)

WATER-QUALITY DATA FOR THE POTOMAC-RARITAN-MAGOTHY AQUIFER SYSTEM, TRENTON TO PENNSVILLE, NEW JERSEY, 1980,
Geological Survey, Trenton, NJ. Water Resources Div.
T. V. Fusillo, and L. M. Voronin.
Available from OFSS, USGS Box 25425, Fed. Ctr. Denver, CO 80225. Paper copy $9.00, Microfiche $4.50. Geological Survey Open-File Report 81-814, May, 1981. 38 p, 1 Fig, 2 Plates, 6 Tab, 19 Ref.

Descriptors: *Water quality, *Groundwater, *Data collections, Unconsolidated aquifers, Aquifer characteristics, Sampling, Chemical analysis, Wells, Well data, Inorganic compounds, Organic compounds, *Water analysis, Coastal plains, *New Jersey, Potomax-Raritan-Magothy aquifer system, Pennsylvania.

Samples for chemical analysis were collected from June to December 1980 from 262 wells tapping the Potomac-Raritan-Magothy aquifer system. The samples were analyzed for common ions, dissolved metals, nutrients, dissolved organic carbon, volatile organic compounds, pH, temperature, and specific conductance. This report contains the results of the analyses, well construction data for the wells sampled, and simple statistical summaries for each parameter. Most parameters showed wide variations in concentration. Concentrations of dissolved organic carbon ranged from 0 to 108 mg/L (milligrams per liter), with a median of 1.7 mg/L. Chloride concentration ranged from 0.8 to 810 mg/L, with a median of 15 mg/L. Iron concentration ranged from 3 micrograms per liter to 79,000 micrograms per liter, with a median of 1,400 micrograms per liter. Detectable concentrations of volatile organic compounds were found in 46 wells, approximately 19 percent of the 246 wells sampled for such compounds. Trichloroethylene and benzene, the most common compounds, were detected in 24 and 18 wells, respectively. The maximum concentrations of several compounds detected include: benzene, 1,960 micrograms per liter; 1,1-dichloroethylene, 670 micrograms per liter; trichloroethylene, 472 micrograms per liter; and tetrachloroethylene, 335 micrograms per liter. QUALITY OF SURFACE WATER IN THE COAL-MINING AREAS OF WESTERN MARYLAND AND ADJACENT AREAS OF PENNSYLVANIA AND WEST VIRGINIA FROM APRIL 1979 TO JUNE 1980,
Geological Survey, Towson, MD. Water Resources Div.
W. W. Staubitz.
Available from OFSS, USGS Box 25425, Fed. Ctr. Denver, CO 80225. Paper copy $13.75, Microfiche $3.50. Geological Survey Open-File Report 81-812, August, 1981. 103 p, 1 Fig, 6 Tab, 7 Ref.

Descriptors: *Water quality, *Strip mines, *Streamflow, *Data collections, Monitoring, Networks, Surface water, Sediment discharge, Coal mining, Water analysis, Benthic fauna, Base flow, *Eastern Coal Province, Area 5, Area 6, North Branch Potomac River, Youghiogheny River, Casselman River, Maryland, Pennsylvania, West Virginia.

The U.S. Geological Survey is monitoring the water quality of streams within the Eastern Coal Province. This report contains streamflow, water-quality, and biological data collected in the North Branch Potomac River basin and in the Maryland portion of the Youghiogheny and Casselman River basins. Data collected from 64 streams from April 1979 to June 1980 are presented in tables. Other sources of hydrologic information within the study area are also described in the report. (USGS)

WATER TYPE AND SUITABILITY OF OKLAHOMA SURFACE WATERS FOR PUBLIC SUPPLY AND IRRIGATION. PART 1: ARKANSAS RIVER MAINSTEM AND VERDIGRIS, NEOSHO, AND ILLINOIS RIVER BASINS THROUGH 1978,
Geological Survey, Oklahoma City, OK. Water Resources Div.
J. D. Stoner.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-142902, Price codes: A14 in paper copy, A01 in microfiche. Geological Survey Water-Resources Investigations 81-33, May, 1981. 297 p, 6 Fig, 3 Tab, 14 Ref.

Descriptors: *Water supply, *Irrigation, *Surface water, *Data collections, *Water quality, Water analysis, Trace elements, Hardness, Water use, *Oklahoma, Arkansas River, Verdigris River basin, Neosho River basin, Illinois River basin.

Water-quality data in the Arkansas River mainstem and the Verdigris, Neosho, and Illinois River basins within Oklahoma were examined for water type and suitability for public water supply and irrigation use. The classification of water type was based on the relation of the major ions: calcium, magnesium, sodium, bicarbonate/carbonate, sulfate, and chloride to each other within the range of measured specific conductance. The judgement of suitability for public supply use was based on the concentration levels and distributions of selected constituents. The Wilcox irrigation classification scheme was used to relate sodium concentrations and the salinity distribution to the use of the water for irrigation. The possibility of phytotoxic effects from boron was discussed where data were available. (USGS)

WATER RESOURCES DATA FOR PENNSYLVANIA, WATER YEAR 1980--VOLUME 1. DELAWARE RIVER BASIN.
Geological Survey, Harrisburg, PA. Water Resources Div.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-190372, Price codes: A16 in paper copy, A01 in microfiche. Geological Survey Water-Data Report PA-80-1, 1981. 341 p, 8 Fig.

Descriptors: *Hydrologic data, *Surface water, *Groundwater, *Water quality, Gaging stations, Streamflow, Flow rates, Sediment transport, Water analysis, Water temperature, Chemical analysis, Lakes, Reservoirs, Wells, Water level, Data collections, Sites, *Pennsylvania, *Delaware River basin.

Water resources data for the 1980 water year for Pennsylvania consist of records of discharge and water quality of streams, elevation and contents of lakes and reservoirs, and water levels of groundwater wells. This volume contains records for water discharge at 73 gaging stations, elevation and contents at 11 lakes and reservoirs, water quality at 39 gaging stations, and water levels at 16 observation wells. Also included are data for 43 crest-stage 28 low-flow, and 43 water-quality partial-record stations. Locations of these sites are shown on figures 4 through 7. Additional water data were collected at various sites not involved in the systematic data-collection program and are published as miscellaneous measurements and analyses. These data together with the data in Volumes 2 and 3 represent that part of the National Water Data System operated by the U.S. Geological Survey and cooperating State, local, and Federal agencies in Pennsylvania. (USGS)
W82-04521

WATER RESOURCES DATA FOR WEST VIRGINIA, WATER YEAR 1980. APPENDIX - COAL AREAS.
Geological Survey, Charleston, WV. Water Resources Div.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-159674, Price codes: A11 in paper copy, A01 in microfiche. Geological Survey Water-Data Report WV-80-A, October, 1981. 228 p, 9 Fig, 8 Tab.

Descriptors: *Coal, *Hydrologic data, *Surface water, *Water quality, Streamflow, Flow rates, Sediments, Water analysis, Water temperature, Chemical analysis, Coal mines, Data collections, Sites, *West Virginia, Coal areas.

Water resources data for the 1980 water year for coal regions of West Virginia consist of discharge and water-quality records collected during two sampling periods at 369 sites. Also included are sediment data from 26 sites. Data were collected as a part of the statewide Coal Hydrology project. (USGS)

WATER RESOURCES DATA FOR LOUISIANA, WATER YEAR 1981--VOLUME 3. COASTAL LOUISIANA.
Geological Survey, Baton Rouge, LA. Water Resources Div.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-129305, Price codes: A14 in paper copy, A01 in microfiche. Geological Survey Water-Data Report LA-81-3, 1981. 218 p, 6 Fig.

Descriptors: *Hydrologic data, *Surface water, *Groundwater, *Water quality, Gaging stations, Streamflow, Flow rates, Sediment transport, Water analysis, Water temperature, Chemical analysis, Lakes, Reservoirs, Wells, Water level, Data collections, Sites, *Louisiana, *Coastal Louisiana.

Water resources data for the 1981 water year for Louisiana consist of records of stage, discharge, and water quality of streams; stage, contents, and water quality of lakes and reservoirs; and water levels and water quality of ground water. This report, in three volumes, contains records for water discharge at 81 gaging stations (including stage for 76 of these stations); stage only for 37 gaging stations and 10 lakes; contents for 1 reservoir; water quality for 142 surface-water stations (including 35 gaging stations), 27 miscellaneous sites, 10 lakes, and 286 wells; and water levels for 679 observation wells. Also included are data for 250 crest-stage and flood-profile partial-record stations. Additional water data were collected at various sites not involved in the systematic data-collection program, and are published as miscellaneous measurements. Records for a few pertinent stations in bordering States are also included in this report. These data represent that part of the National Water Data System operated by the U.S. Geological Survey and cooperating State and Federal agencies in Louisiana. (USGS)

RIDING MILL PUMPING STATION,
D. J. Banks, D. F. H. Pain, and W. Banks.
Journal of the Institution of Water Engineers and Scientists, Vol 35, No 6, p 463-482, 1981. 7 Fig, 6 Ref.

Descriptors: *Water conveyance, *Construction, Design criteria, Maintenance, Pumps, *Water supply systems, Kielder Water Scheme, Pumping plants, River Tyne, River Wear, River Trees, *England, Water transfer, Pipelines, Water demand.

The large pumping capacity, intermittent usage, and large size of the Riding Mill pumping station have demanded reconsideration of usual water supply practices. The operating concepts, design development, and plant selection are described for this plant, which is part of the Kielder Water Scheme and is designed for bulk transfer of water from the River Tyne to the Rivers Wear and Trees. Tyne water is relatively unpolluted, with virtually no suspended solids. Therefore it was possible to use single-stage pumping and thus avoid the major costs of low-lift pumps and large settling tanks. Debris and sediment intake problems was reduced by arranging the draw-off to avoid obstruction to river flow and keeping the draw-off sill above river bed level and the intake velocity as low as possible. Fine mesh band screens were placed in a chamber back from the river frontage to protect the pumps and exclude smolts. Trash bars were selected rather than penstock openings. The pumping station was designed for unattended automatic operation. A special pipeline filling pump was installed. (Baker-FRC)

APPROXIMATE SIZING OF RESERVOIRS FOR DETENTION TIME,
Commonwealth Tech, Inc., Lexington, KY.
J. S. Tapp, A. D. Ward, and B. J. Barfield.
Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 108, No HY1, p 17-23, January, 1982. 5 Fig, 1 Tab, 6 Ref.

Descriptors: *Detention times, *Reservoir design, *Sedimentation basins, Design criteria, *Sediment control, Spillways, Hydrographs, Storms, Rainfall, Reservoir storage.

Design of sediment control reservoirs has been facilitated by a new procedure using triangular hydroraphs to give a first approximation of the peak outflow and storage volume necessary to give a desired detention time. Only 1 or 2 trials are necessary. The size of the spillway system and the sediment pond design may be hand calculated for a given detention time. The triangles approximate the inflow-outflow hydrographs. This method was compared with the detailed computer model DEPOSITS. After modifications in the equations, the standard error was an acceptable 0.028 watershed in. The procedure is applicable to reservoirs with principal spillway crests located at the top of the sediment storage pool. (Cassar-FRC)

MICRO HYDROPOWER IN THE USA,
EG and G Idaho, Inc., Idaho Falls.
R. O. Haroldsen, and F. B. Simpson.
International Water Power and Dam Construction, Vol 33, No 11, p 48-50, November, 1981. 1 Fig.

Descriptors: *Hydroelectric plants, *Powerplants, *Economic evaluation, Water resources development, Rural areas, Diesel units, Case studies.

Micro hydropower is not expected to make a major contribution to the nation's energy production. However, developers may gain a measure of independence and security, especially in isolated areas where small diesel units are used. Two plants are described. The 50 kW plant at Bliss, Idaho, produces $1000 per month of power from a $40,000 capital investment. A low head installation (effective head 2 m) at Aumsville, Oregon, produces a maximum 23 kW out of a design 40 kW. Many other problems make this site a poor investment, producing only $100-200 of power monthly. There is a need for reasonable standards to cover connections with the utility power grid and for better information on site assessment, equipment, institutional requirements, and available technology. OBTAINING LAYOUT OF WATER DISTRIBUTION SYSTEMS,
Department of the Air Force, Washington, DC.
W. F. Rowell, and J. W. Barnes.
Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 108, No HY1, p 137-148, January, 1982. 4 Fig, 17 Ref.

Descriptors: *Network design, Pipes, *Water distribution, Water quality control, *Model studies,

LIBRARY U. OF I., URBANA-CHAMPAIGN

Water demand, Water conveyance, Water mains, Design criteria, *Water supply systems.

A procedure to help with selecting a water distribution network layout involves two steps. The first step uses a nonlinear programming model to select an economical tree layout for the larger diameter pipe links to provide service under normal demand. The second step uses an integer programming model to choose loop-forming redundant links and corresponding link diameters to provide adequate capacity in case the large diameter primary link system fails. The second level system reduces water stagnation, retards sediment accumulation, facilitates pipe cleaning, and provides alternate paths. The procedure is illustrated using a two-source water distribution system. (Cassar-FRC)

SMALL HYDRO SCHEMES FOR PRIVATE DEVELOPERS,
Hydro Watts Inc., Washington Grove, MD.
S. L. Bierman, and R. A. Klempner.
International Water Power and Dam Construction, Vol 33, No 11, p 35-36, November, 1981. 1 Tab.

Descriptors: *Hydroelectric plants, *Powerplants, *Dams, Hydraulic structures, *Cost analysis, Feasibility studies, Costs.

Incentives for private developers to invest small (less than 5 MW) hydropower schemes include rising fuel prices, governmental financial assistance, and the obligation of utilities to offer to buy output. There are 700 existing U.S. dams which are feasible to develop. Average head is 15 m; average flow, 10 cu m per sec; and average reservoir surface area, 2.4 million sq m. Development costs, which range up to $2000 per kW of installed capacity, are quipment, 33% of total costs; civil works. 40-50%; engineering and interest during construction, 10-15%; and contingency, 10%. Operating costs are variable and may be as high as 6 cents per kWh. (Cassar-FRC)
W82-04327

RURAL POWER SCHEMES IN PAKISTAN,
Peshawar Univ. (Pakistan). Dept. of Electrical Engineering.
M. Abdullah, and A. R. Inversin.
International Water Power and Dam Construction, Vol 33, No 11, p 23-25, November, 1981. 2 Fig.

Descriptors: *Rural areas, *Hydroelectric plants, *Pakistan, *Developing countries, Design criteria, Powerplants, Hydraulic structures, Dams.

In the mountainous remote regions of northern Pakistan there are 22 5-15 kW microhydropower schemes in operation. Costs per installed kilowatt are $250-400. These projects are built by villagers from local materials. No engineering drawings are provided. Technical assistance is given by the Appropriate Technology Development Organization, a government agency. A typical installation has an intake consisting of a low stone weir and unlined headrace. Penstocks, usually 5-15 m long, are made of steel pipe or oil drums. The cross-flow turbine is made locally from strips of steel or pieces of pipe. Generators, presently made in China, will be manufactured locally in the near future, saving about 25% in costs. The electricity is generally used for lighting and to run machines in cottage industries. (Cassar-FRC)
W82-04328

PUMPED OUTLETS FOR DRAINAGE SYSTEMS,
A. T. Corey.
Transactions of the ASAE, Vol 24, No 6, p 1504-1507, November/December, 1981. 1 Fig, 3 Ref.

Descriptors: *Drainage systems, *Sumps, *Storage capacity, Design criteria, *Pumps, *Tile drainage, Subsurface drainage, Conduits.

The size and cost of storage capacity of sumps for pumped outlets of subsurface drainage systems can be reduced by using the disposal tile as part of the storage system. This is feasible where the tiles can be below the grade of the collector tiles so that submergence of the main drain does not block discharge from the laterals. The maximm discharge capacity of the disposal tile should be nearly that of the pump, or else the pump motor will cycle excessively when the tile is flowing nearly full. Equations and a method for designing necessary sump storage are given. (Cassar-FRC)
W82-04364

OPTIMAL DESIGN OF URBAN STORM WATER DRAINAGE SYSTEMS,
New South Wales Univ., Kensington (Australia). School of Civil Engineering.
D. K. Robinson, and J. W. Labadie.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-211491, Price codes: A02 in paper copy, A01 in microfiche. In: Proceedings 1981 International Symposium on Urban Hydrology, Hydraulics, and Sdiment Control, July 27-30, 1981. University of Kentucky, Lexington. 12 p, 4 Fig, 6 Tab, 12 Ref. OWRT C-90037-U(0507)(1). 14-34-0001-0507.

Descriptors: *Urban drainage, *Storm sewers, Minimum cost, Storm sewer design, Dynamic programming, *Design criteria, *Costs, Systems analysis, Comparison studies.

Several researchers have developed screening models for minimizing the cost of sizing and vertical alignment of storm sewer systems. One of the disadvantages of these models is that they are designed with specific physical/economic assumptions in mind, as well as specific types of cost functions. These assumptions are effectively hardwird into the program, which militates against modifying the program to suit situations not covered in the original assumptions. A generalized dynamic programming computer code has been developed at Colorado State University called CSUDP. A library of subroutines is being prepared as an adjunct to the basic code for solving a wide range of civil engineering problems. One of the packages includes a set of subroutines for storm sewer design. The coding includes data management routines for convenience to the user not familiar with dynamic programming. The code can consider complex branching networks with up to three pipes entering a given manhole. Default options are available for excavation, pipe, and manhole cost functions. If the costs for a particular case have a significantly different structure, the user can supply his own subroutine. There are several other default options which make this program extremely convenient for normal design conditions, as well as usable for unique problems. Extensive comparisons have been made between available published results of other dynamic programming screening models and the CSUDP package. Results are extremely close. The one comparison resulting in a large deviation was due to slightly differing hydraulic and cost assumptions, which caused larger commercial pipe sizes to be chosen by CSUDP, even though actual pipe requirements deviated little.
W82-04414

JET INJECTIONS FOR OPTIMUM MIXING IN PIPE FLOW,
Turner, Collie and Braden, Inc., Houston, TX.
S. D. Fitzgerald, and E. R. Holley.
Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 107, No HY10, p 1179-1195, October, 1981. 5 Fig, 11 Ref. OWRT A-091-ILL.

Descriptors: *Pipe flow, *Jets, *Mixing, Optimization, Pipes, Uniform flow, Water currents, Pipelines.

The use of jet injections was evaluated to provide initial mixing and thereby hasten the mixing process between a miscible substance and water flowing in a piepline. The study experimentally investigated several jet injection systems to determine their mixing characteristics, identified those systems providing the most rapid mixing, determined optimum operating conditions, and investigated the effects which secondary currents had on the mixing. For uniform pipe flow with a given number and orientation of jets, the ratio of jet momentum flux to the pipe-flow momentum flux was the parameter indicative of the mixing induced by the jets. Under many circumstances, it may be practical to consider only a 90 deg angle of injection. Experiments also investigated two diametrically opposed 90 deg jets in uniform flow. Optimum mixing was obtained when the momentum ratio for each jet was on the order of one-half of the optimum momentum ratio for a single jet injection. Also, experiments on a pipe flow with an induced secondary current indicated that the use of two or more jets would provide a factor of safety against the effects of unknown secondary currents. METHODS FOR ASSESSMENT OF STREAM-RELATED HAZARDS TO HIGHWAYS AND BRIDGES,
Colorado State Univ., Fort Collins. Engineering Research Center.
H. W. Shen, S. A. Schumm, J. D. Nelson, D. O. Doehring, and M. M. Skimmer.
Available from the National Technical Information Service, Springfield, VA 22161 as PB81-219750, Price codes: A12 in paper copy, A01 in microfiche. Federal Highway Administration Report No FHWA/RD-80/160, March, 1981. 252 p, 32 Fig, 3 Tab, 51 Ref, 4 Append. DOT-FH-11-9396.

Descriptors: *Bridge design, *Highways, *Hydraulic design, *Stream erosion, *Bank erosion, Sedimentation, Deposition, Bridge failure, Land use, Remote sensing, Slope stability, Stream banks, Avulsion, Aggradation, Meanders, Morphology, Scour, Waves, Flotsam.

River behavior at a highway crossing depends not only on the stability of that particular river reach, but also on the behavior of the entire fluvial system. A complete evaluation of hydraulic hazards cannot be solely based on on-site hydrologic, hydraulic and geomorphic factors; but must also include insight into historic trends, synoptic considerations of basin characteristics, and anticipation of future changes. Because determination of stream-related hazards is a complex task, it is beneficial to generalize relative stability based on stream type. Streams can be divided into five types based on channel pattern and mode of sediment deposition. Each stream type exhibits its own characteristic stability. After evaluating stream variables, a list of potential stream hazards can be developed. Stream-related hazards include: degradation and scour; nickpoint migration; bank erosion; aggradation and fill; downfilling and backfilling; berming; meander growth and shift; channel bars and islands; cutoffs; avulsion; river-metamorphosis; floating objects; waves and surges. Each potential hazard can be evaluated on an individual basis and properly considered in either the design of a new crossing or maintenance of an existing one. Numerous evaluation methods are available to hydraulic engineers that have not been fully utilized. Methods such as remote sensing, land use evaluation and slope stability analysis should not be overlooked. (Moore-SRC)

THE DESIGN OF ENCROACHMENTS ON FLOOD PLAINS USING RISK ANALYSIS,
Federal Highway Administration, Washington, DC. Office of Engineering.
M. L. Corry, J. S. Jones, and P. L. Thompson.
Hydraulic Engineering Circular No 17, October, 1980. 134 p, 15 Fig, 14 Tab, 23 Ref, 3 Append.

Descriptors: *Flood plains, *Bridge design, *Risks, *Highways, *Flood damage, *Cost analysis, Culverts, Scour, Channel erosion, Economic aspects,

Design criteria, Embankments, Dikes, Earthworks, Alternative planning.

The design of all flood plain encroachments should include an evaluation of the inherent flood related risks to the highway facility and to the surrounding property. When this evaluation indicates that the risk warrants additional study, a detailed analysis of alternative designs is necessary in order to determine that design with the least total expected cost (LTEC) to the public. An essential ingredient in the LTEC design concept is risk analysis. All quantifiable losses are included in the risk analysis. These may involve damage to structures, embankments, surrounding property, traffic related losses and scour or stream channel damage. The product of the risk analysis is the annual economic risk associated with each design strategy. The sum of the annual economic risk and the annual capital costs results in the total expected cost (TEC) for each design strategy. Comparison of the TEC's for all design strategies allows the designer to select the LTEC or optimum design. Although the emphasis in this manual is on bridge crossings, the LTEC decisionmaking process concept is applicable to other drainage features. For example, it may be utilized in the design evaluation of culverts, longitudinal encroachments, countermeasures and foundation elevations. (Moore-SRC)
W82-04631

APPLICATION OF THE SOUTHWELL PLOT METHOD TO THE INSPECTION AND TESTING OF BURIED FLEXIBLE PIPES,
Cambridge Univ. (England).
A. J. Valsangkar, A. M. Britto, and M. J. Gunn.
Proceedings of the Institution of Civil Engineers, Part 2: Research and Theory, Vol 71, No 1, p 63-82, March, 1981. 14 Fig, 5 Tab.

Descriptors: *Pipes, *Buckling, *Deformation, Nondestructive tests, Southwell plot, *Stress, Flexibility, Inspection, Safety, Soil mechanics, Soil strength, Pipelines, *Design criteria.

A nondestructive method for estimating the buckling load of buried flexible pipes uses the Southwell plot. It allows estimation of a generalized out-of-roundness and predicts a buckling load. The difference between predicted and actual buckling loads is greater at larger initial out-of-roundness values for the buried pipe. A method is presented for estimating the safe failure load from the Southwell plot buckling load and the generalized out-of-roundness. Experimental data produced by other investigators on the stability of buried pipes were used to test the validity of this method. Very flexible pipes (effective stiffness < 0.5 kN per sq m) in dense sand produce small deflections before failure and cannot be reliably analyzed by the Southwell plot method. Pipes with effective stiffness of 3.62-157.1 kN per sq m may be loaded to about two thirds of their buckling load, at which stage the Southwell plot is linear. (Cassar-FRC)

ADOPTING SEWERS,
Southern Water Authority (England).
J. Budleigh.
Water, No 42, p 20-21, 1982. 2 Ref.

Descriptors: *Sewer systems, *Design criteria, Management, *Construction, *Housing, Land development.

Traditionally sewers are constructed by the developers of housing projects and offered to the water authority for adoption when finished in much the same way as estate roads. The ground rules for adoption are laid down in Section 17 and 18 of the Public Health Act of 1936. Two alternative arrangements are offered to the developer. In Section 17 he may design and construct the sewers as he sees fit and then offer them for adoption. Section 18 provides for a clear cut agreement prior to construction between the developer and the sewerage authority. A considerable step forward would be provided for by a national agreement on the standards and conditions which must be met by the water and housebuilding industries. Such an agreement has been reached. As far as the design and layout of sewers is concerned, the standards required are generally in line with the present British Standard Code of Practice for sewerage, CP2005. One long standing problem has been the supervision allowed by Section 18 on the part of the sewerage authority. The building company generally does not object to the fact that supervisors from the sewerage authority are present, but does object to having to pay for this. Another problem concerns the provision of a guarantee to the authority that the builder would actually carry on and finish the sewers as agreed. The third problem has to do with sewage pumping stations. These problems are dealt with in the housing developer's guide. (Baker-FRC)

JAMES BAY SPILLWAYS AND CONTROL STRUCTURES,
La Societe d'Energie de la Baie James, Montreal (Quebec).
K. R. Ludwig, and R. T. Olive.
Journal of the Energy Division, Proceedings of the American Society of Civil Engineers, Vol 107, No EY2, p 183-198, December, 1981. 6 Fig, 1 Tab, 9 Ref.

Descriptors: *Spillways, *Flow control, *Hydraulic gates, James Bay, *La Grande Complex, *Quebec, Hydraulic structures, *Reservoirs, Water resources development, Gates, Hydraulic design, Flow velocity, Design criteria, Concrete, Maintenance, Cold weather construction, Bridges, Ice, Dam construction, Hydroelectric plants.

The structural conception of the major spillways and control structures of Quebec's six-reservoir La Grande Complex is summarized. All spillways and control structures contain a gate structure and a downstream discharge facility. Concrete has been used only where necessary to control flow, since the resistance of rock in this region is superior to concrete. The standardized gate opening is 40 ft, and all gates are of the flat, wheeled, vertical-lift type. The number of gates varies with the discharge capacities. Flow velocities have been limited to 60 ft per sec at the sill and 100 ft per sec at the downstream end for structures in intermittent operation. Control structures in use for prolonged periods are limited to a maximum velocity of 60 ft per sec for no more than 10% of the time. Drainage systems are located in areas protected against freezing, and gates are equipped with electric deicers. The dam bridge, aligned with the crest to either side of the spillway, is upstream of the stoplogs. Discharge from the gate structures is handled in a variety of ways, depending on the location. These include stilling basins, rock cut channels to the lake or river, chutes, flip buckets, intervening lakes, plunge pools, and combinations of these. (Cassar-FRC)

TAPERED INLET DESIGN USING SPECIFIC ENERGY CURVES,
Iowa State Univ., Ames. Dept. of Civil Engineering.
R. L. Rossmiller, and M. D. Dougal.
Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 108, No HY1, p 127-135, January, 1982. 4 Fig, 5 Ref.

Descriptors: *Design criteria, *Culverts, *Inlets, Hydraulic structures, Water conveyance, Conduits, Pipes, Highways, Iowa, Specific energy curves, Economic aspects.

Design charts for the hydraulic design of tapered inlet highway culverts are given for both rectangular (box) and circular (pipe) sections. Errors, design time, and construction costs are greatly reduced by use of these charts. In Iowa savings from the use of tapered culverts at individual sites range from $1000 to over $100,000, for a total of millions of dollars over the past few years. The raised inlet culverts can form ponds for recreation or stock watering and help stabilize the upstream channel slope. For box culverts the chart plots depth in feet against specific energy head in feet for different ratios of design discharge to width of culvert. For pipe culverts, depth to pipe diameter ratio is plotted against specific energy to diameter ratio for different values of Q squared divided by D to the 5th power, where Q = design discharge and D = diameter of pipe. ASYMPTOTIC SOLUTION FOR DAM-BREAK PROBLEM,
Cantebury Univ., Christchurch (New Zealand).
B. Hunt.
Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 108, No HY1, p 115-126, January, 1982. 6 Fig, 9 Ref.

Descriptors: *Dam failure, *Kinematic wave theory, *Flood waves, Wave propagation, Hydraulics, Reservoir releases, Water flow.

The kinematic wave approximation is used to obtain a simple, closed-form solution for the catastrophic failure of a dam upon a dry, sloping channel. The solution validity is investigated by computing orders of magnitude for neglected terms in the equations of motion and by comparing the solution with the results of previously calculated numerical solutions and with experimentap results. These calculations and comparisons suggest that the kinematic wave solution becomes asymptotically valid after the flood wave has advanced about four reservoirlengths downstream. (Author abstract)

Acceptance of water-source heat pumps has been slow because of potential environmental impacts

LIBRARY U. OF I.- URBANA-CHAMPAIGN

(water-level declines, subsidence, injecting substances into aquifers), cost, and lack of design data. The purpose of this work was to determine proper well spacing for single sets of twin wells, and for multiple sets; to examine the feasibility of their use in two Louisiana parishes; and to determine the potential use, economics, and environmental impact of water-source heat pumps. The use of twin wells--one to pump water, one to recharge the aquifer--precludes groundwater declines and, if properly spaced, avoids altering the groundwater temperature. The well used for production in summer is used for injection in winter, and vice-versa. A table is given to approximate the needed spacing between the wells. Even using an annual interest rate of 14%, a water-source heat pump and single well combination is often the most effective system for heating/cooling. In many areas of the two parishes studied, this system will be economical, especially in areas underlain by groundwater at shallow depth. Also, if properly designed and built, twin well systems will have no environmental impact on the biosphere and only minimal thermal impact on the source aquifers. It is recommended that no legislation be adopted that would prevent use of the system for those wanting to conserve energy; that research be encouraged to achieve higher coefficients of performance by use of a new working fluid, an increase in the throughput of water, or by reducing head loss in a unit; and that a streamline-tracking program be prepared to compute the consequences of operating large numbers of well pairs. THE VORTEX SCOUR MECHANISM AT BRIDGE PIERS,
Zakir Husain Coll. of Engineering and Technology, Aligarh (India).
A. Qadar.
Proceedings of the Institution of Civil Engineers, Part 2: Research and Theory, Vol 71, No 3, p 739-757, September, 1981. 13 Fig, 8 Tab, 10 Ref.

Descriptors: *Scour, *Vortices, *Erosion, Sediment transport, *Piers, Rivers, Hydraulics, Riprap, Bridges, Flow around objects, Flow characteristics, *Bridge piers.

A tilting non-recirculating flume (0.3 m wide x 0.45 m deep x 5 m long) was used to study the vortex scour mechanism at bridge piers. First, experiments were performed on a rigid bed to study the behavior of the scouring vortex. Second, a sand bed was installed to measure the depth of scour holes. Results of field tests at several bridges in India and Canada were also reported. Several conclusions were developed from the observations. The basic mechanism of localized scours was identified as a secondary circulation caused by an upstream flow separation ahead of the pier. The maximum depth of the scour is a function of the strength of the vortex which develops ahead of the pier and is described in an equation containing the following terms: initial strength of vortex, an experimentally determined exponent to sediments up to 0.5 mm in diameter. For larger-sized sediments, roughness elements cause a reduction in scour. Although the depth of the approach flow has little measurable effect on maximum scour depth, there is a minimum depth of flow necessary for full development of vortex action. Scouring may be prevented or reduced by installing large-size riprap around piers or by weakening the basic mechanisms. (Cassar-FRC)

FLOW RESONANCE IN RIGID PIPES WITH REGULAR LONGITUDINAL CORRUGATIONS,
Thessaloniki Univ., Salonika (Greece). Dept. of Hydraulics.
P. Latinopoulos, and D. K. Tolikas.
Proceedings of the Institution of Civil Engineers, Part 2: Research and Theory, Vol 71, No 1, p 263-267, March, 1981. 3 Ref.

Descriptors: *Pipe flow, *Resonance, *Flow characteristics, Wave propagation, Hydraulics, Water hammer.

The method of multiple scales was used to derive a uniform first order expansion for the condition of resonance in a corrugated pipe. Weak waves caused by small undulations on the pipe wall can be generated. Under certain conditions a resonance occurs that is independent of water hammer or resonance due to reflections at the boundaries of the system. Resonance can be expected when the wave number of the wall undulations matches the difference of the wave number of any two propagating nodes which are strongly coupled and travel unattenuated along the pipe. ANALYSIS OF THE HYDRAULIC JUMP WITHIN A DIVERGING RECTANGULAR CHANNEL,
University of Wales Inst. of Science and Technology, Cardiff.
P. W. France.
Proceedings of the Institution of Civil Engineers, Part 2: Research and Theory, Vol 71, No 2, p 369-378, June, 1981. 6 Fig, 8 Ref.

Descriptors: *Hydraulic jump, *Spillways, Dam design, *Channel flow, Flow characteristics, Froude number, Model studies.

Properties of hydraulic jumps with parallel-sided channels and gradually diverging rectangular channels were compared theoretically and in laboratory flume studies. An equation was developed to predict the sequent depth in a diverging channel. The relative energy loss in a diverging channel was 12% higher than in a parallel-sided channel for the same Froude number. Although the energy loss was independent of the angle of divergence, it was a function of the sequent radius ratio. The lengths of diverging jumps were about 40% less than the straight-sided jumps for the same Froude number. The sensitivity of the jump became more stable as the angle of divergence increased. SIMULATION OF SURGES AFTER REMOVAL OF A SEPARATING BARRIER BETWEEN SHALLOWER AND DEEPER BODIES OF WATER,
University of Strathclyde, Glasgow (Scotland).
D. I. H. Barr, and M. M. Das.
Proceedings of the Institution of Civil Engineers, Part 2: Research and Theory, Vol 71, No 3, p 911-919, September, 1981. 9 Fig, 7 Ref.

Descriptors: *Surges, *Barriers, *Flow characteristics, Hydraulics, Water level, Channel flow, Roughness, Water depth, Simulation analysis.

Surges produced after removal of a barrier separating water bodies with surfaces at different levels were numerically simulated. The equations were based on the St. Venant equations as applied to the dry bed dam burst case. Laboratory measurements were taken in rectangular channels with both smooth and artificially roughened surfaces. Laboratory data were compared with numerical simulations on three bases: surface profiles, depth hydrographs, and front trajectories. Agreement between observed and calculated values was good. Increased rates of damping and lagging of the surge front were seen both in the smaller-scale experiments and in roughened channels. (Cassar-FRC)

Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 108, No HY1, p 95-114, January, 1982. 15 Fig, 2 Tab, 22 Ref.

Descriptors: *Slope stability, *Tractive forces, *Sediment transport, Channel erosion, *Stream banks, Sand, Erosion, Sedimentation, Flow velocity, Critical velocity, Turbulent flow, Drag, Soil mechanics, Hydraulics, Channel scour.

Although several criteria have been theoretically proposed for the critical shear stress of noncohesive sediment on side slopes of river and channel banks, no laboratory work on this problem has been reported. This paper presents a theoretical study on the incipient motion of sediment particles on side slopes, accounting for the effects o the viscous sublayer, turbulence, and lift force. A laterally tilting wind tunnel was used to measure critical shear stress on side slopes from 0 to 40 degrees. Wind velocity varied from 0 to 30 m per sec. Two grades of noncohesive sand with median diameters of 1.3 and 0.42 mm were used in the experiment. Results of the wind tunnel tests confirmed the theory presented in this paper. On level beds the incipient motion of sand particles was essentially stochastic for the 1.3 mm sand, with a few particles first set in motion in isolated spots. The 0.42 mm sand particles moved intermittently as a unit. Although the lift force can be neglected when using the most probable values of critical tractive forces, it should be included for safety. The present equation does not account for disturbances such as sand waves, channel irregularities, and bends. (Cassar-FRC)

EVALUATION OF A CHIMNEY DRAIN DESIGN IN AN EARTHFILL DAM,
Geological Survey, Doraville, GA.
M. L. Maslia, and M. M. Aral.
Ground Water, Vol 20, No 1, p 22-31, 1982. 7 Fig, 3 Tab, 24 Ref.

Descriptors: *Mathematical models, *Earth dams, *Drainage systems, *Performance evaluation, Soil physical properties, Clays, Sand filters, Silt, Model studies, Mathematical studies, Numerical analysis, Pressure head, Seepage, *Wallace Dam, Georgia.

The finite element Galerkin method was used to formulate a numerical model to study the performance of a vertical drainage filter in a clay fill zone of the Wallace Dam on the Oconee River, Georgia. The resulting model was applied to determine the steady-state saturated-unsaturated seepage characteristics at Station 58 + 00 on the west dike of the earthfill dam. Numerical results for the four cases (clay fill, sand filter, silty sand, and weathered) analyzed define the location of the zero pressure isobar and total hydraulic head values ranging from 130 m to 11 m. Using a saturated horizontal hydraulic conductivity of 8.64 cm/day, a maximum seepage velocity of 0.80 m/day was calculated, resulting in a maximum seepage rate of .752 cu cm/sec. An average pressure head reduction of 16 m from the upstream to the downstream side of the dam was determined from hydrostatic uplift forces along the base of the dam. When local seepage velocities were compared to critical seepage velocities inside of an upstream of the filter, safety factors against piping ranging from 0.3 to 3.7 were found. (Geiger-FRC)

Descriptors: *Filters, *Dam design, *Cores, Sand filters, Soil filters, Clays, Dam failure, Soil mechanics, Grading, Permeability, Sediment sorting, Erosion, Cracks, *Balderhead Dam, *England.

The failure of a filter drain in the clay core of Balderhead Dam, Northern England, prompted a study of filter effectiveness and design. Although the grading of the crushed limestone filter material conformed to accepted designs, the possibility of cracks in the clay core had not been considered. In the Balderhead Dam erosion damage developed above a crack in the clay core. The damage zone contained lenses and other signs of segregation by water action. In some sections of the crack coarse particles accumulated, allowing small soil particles to be lost and enlarging the crack. A 'perfect' filter was designed for the Cow Green Dam and the Empsingham Dam to retain the smallest particles (in this case clay flocs) that can arise during erosion. Laboratory tests helped determine that natural, unwashed sand was suitable as the fine filter. An experimental relationship was found between the size of the particle retained by the filter and its permeability. In the laboratory uniformly-sized filter materials produced fail-no results. Graded filters showed a range during which slow clogging occurred. Permeability appears to be a better method of describing the retention characteristics of a filter than grading. (Cassar-FRC)

ENGINEERING IN CATFISH PRODUCTION,
P. Forsythe.
Agricultural Engineering, Vol 61, No 6, p 18-21, June, 1980.

Descriptors: *Fisheries, *Catfish, *Catfish farming, Catfish ponds, Fish harvest, Water pollution sources, Fish farming, Food processing wastes.

Scientifically managed catfish pond systems are used to produce an average yield of 3000 lb/acre. Optimum pond efficiency results from a layout of 8 ponds per 160 acre area each 660 ft by 1320 ft. The ponds are confined by levees having a 14 ft top width and 3:1 side slopes providing 2 ft of freeboard. The water area is about 17 acres. Th drainage of ponds at harvest creates significant shock loads to streams. The unused catfish feed plus wastes provides an enriched discharge. When fish are processed, processing wastes are treated usually in oxidation lagoons and discharged into city treatment systems. The handling and disposal of processing wastes needs the most attention from agricultural engineers. There is a tremendous opportunity to utilize these thousands of tons of fish protein. The effects on water quality of pond draining also need further investigation. (Small-FRC)

STATUS REPORT ON STRIPED BASS ANALYSES,
California State Dept. of Fish and Game, Sacramento.
Staff report prepared for the State Water Resources Control Board, Sacramento, California, January 20, 1982. 47 p 21 Fig, 10 Tab.

Descriptors: *Fish populations, *Bass, *Fish food organisms, *Fish diets, Fish eggs, Regression analysis, Correlation analysis, Diversion, Fish foods, Food chains, Phytoplankton, Zooplankton, Distribution patterns, Powerplants, Striped bass, *California.

In 1976, the California Department of Fish and Game (DFG) submitted evidence to the State Water Resources Control board indicating that the abundance of young striped bass was largely controlled by the magnitude of Delat outflow and losses in water diversions by the Central Valley Project and the State Water Project. When the abundance of bass was lower than DFG's expectations, the evidence was reexamined. Four hypotheses were advanced--increased competition, diversion, food abundance, and outflow. Most testing used correlation or multiple regression analyses, but a limiting factor of these approaches was that they only determined whether variables vary in a similar manner. None of the hypotheses described the actual mechanisms controlling striped bass abundance since 1959. Other hypotheses are being tested. However, a common theme was the variations in Delta outflow in spring/early summer have a major effect on abundance. High flows spread striped bass over a larger area and expansion of habitat reduces intraspecific competition and, thus, survival. High flows also probably increase food supply for young bass. Several regression analyses indicate that stock size, not food supply, may have caused the unusually low abundance of striped bass since 1976, but that hypothesis, too, has been questioned because bass are so prolific and because of evidence of stock size limitation elsewhere. A basic problem is that striped bass populations have been increasing recently, so any variable with a declining trend is correlated with young bass abundance whether a cause and effect relationship exists or not. (Atkins-Omniplan)

10B. Reference and Retrieval

SEARCH: A GAGED WATERSHED INVENTORY,
State Univ. of New York at Syracuse. Coll. of Environmental Science and Forestry.
P. E. Black.
Water Resources Bulletin, Vol 16, No 5, p 894-899, October, 1980. 4 Fig.

Descriptors: *Information retrieval, *Watersheds, Computers, Surveys, Information systems, Hydrologic data collections, Data collections, Data storage and retrieval, *New York, *Streamflow, *Gaging stations.

The purpose of this paper is to provide the potential user of SEARCH with the information needed to implement its use. The purpose of the program is to provide a ready inventory and search of all gaged streams in New York along with a compilation of major parameters upon which a decision to use records from such a gage might be based. The method is adaptable to any other state or region. The method as described is adapted to an APL interactive terminal, allowing the operator to thoroughly search a large set of gaged watersheds to find sources of comparable hydrologic data for detailed analysis. Bases of the search include drainage basin size and elevation and geographical and temporal parameters. (Baker-FRC)

TNRIS: A SOURCE FOR WATER-RELATED DATA IN TEXAS.
Southwest and Texas Water Works Journal, Vol 63, No 4, p 10-11, July, 1981. 1 Fig, 2 Tab.

Descriptors: *Data storage and retrieval, Information systems, Weather, Water quality, Water supply, Wells, Precipitation, *Texas, TNRIS.

The Texas Natural Resources Information System (TNRIS) stores, processes, and disseminates data and information on Texas' water and other natural resources to State agencies, other governmental agencies, universities, and the public. The system provides access to hydrological, meteorological, geological, biological, socioeconomic, and base data located in more than 300 automated files and over 150 manual files. Base data includes maps and remotely sensed data. TNRIS data files cover such areas as daily and monthly precipitation, daily pan evaporation, daily surface water conductance, surface water quality, daily suspended sediment, and water well measurements. Data for these files are supplied by the National Weather Service, the U.S. Geological Survey, the International Boundary and Water Commission, and Texas State agencies. In addition, TNRIS interfaces with data bases maintained by the U.S. Geological Survey, the Environmental Protection Agency, the Department of Commerce, the Department of Agriculture, and the Department of Energy. TNRIS is capable of providing computer-printed reports, graphic outputs, interface with remote terminals, statistical packages, computer-generated microform, geocoding, analysis of remotely sensed data, catalogs and indices, information on availability of specialized data, and ordering services. The System also conducts a variety of remote sensing and cartographic activities. TNRIS can be assessed

AN INTERACTIVE DATA MANAGEMENT SYSTEM FOR RIVER WATER QUALITY DATA,
Michigan Univ., Ann Arbor. School of Public Health.
R. A Deininger.
Water Research, Vol 16, No 1, p 31-36, January, 1982. 2 Fig, 13 Tab, 3 Ref.

Descriptors: *Water quality, *Data storage and retrieval, *Information systems, Computers, Rivers, Statistical analysis, *Ohio River basin.

A water quality data bank for interactive use is described. Unlike the STORET, NAQUADAT, and EIS systems in the U.S., Canada, and Scandinavia, respectively, this system allows the user to search, update, retrieve, and analyze data from a computer terminal without the help of specially trained personnel. This system, located at the University of Michigan, can be accessed by local telephone numbers in 100 U.S. and Canadian cities and by the TELENET system from European cities. The system is illustrated by a sample problem using a small water quality data base with values for 9 selected parameters from 35 monitoring stations in the Ohio River Basin. Statistical analysis can be performed using the MIDAS software system. Graphs may be displayed on a television screen. (Cassar-FRC)

W82-04720 5B

AMMONIA
Relative Effects on Stream Biota of Chlorine and Ammonia Occurring in Secondary Sewage,
W82-04409 5C

ANAEROBIC DIGESTION
Anaerobic Digestion of Farm Wastes: A Review - Part 2,
W82-04347 5E

Terminal Reactions in the Anaerobic Digestion of Animal Waste,
W82-04454 5D

Microbiology of Anaerobic Digestors for Wastewater Purification. (Microbiologie des Digesteurs Anaerobies de l'Epuration des eaux Residuaires),
W82-04544 5D

The Importance of the Solids Content of the Sludge in Anaerobic Alkaline Digestion (Die Bedeutung des Feststoffgehalts bei der Schlammfaulung),
W82-04549 5D

ANAEROBIC TREATMENT
Treatment of Sulfite Evaporation Condensate with an Anaerobic Reactor,
W82-04419 5D

ANIMAL WASTES
Terminal Reactions in the Anaerobic Digestion of Animal Waste,
W82-04454 5D

ANTARCTIC
Biogenic Calcite Structures Forming in Lake Fryxell, Antarctica,
W82-04638 2H

APPROPRIATION
Recent Developments in Colorado Groundwater Law,
W82-04679 6E

Bubb v. Christensen: The Rights of the Private Landowner Yield to the Rights of the Water Appropriator Under the Colorado Doctrine,
W82-04680 6E

AQUACULTURE
Aquacultural Approaches to Recycling of Dissolved Nutrients in Secondarily Treated Domestic Wastewater--IV. Conclusions, Design and Operational Considerations for Artificial Food Chains,
W82-04369 5D

Aquacultural Approaches to Recycling of Dissolved Nutrients in Secondarily Treated Domestic Wastewaters--III. Uptake of Dissolved Heavy Metals by Artificial Food Chains,
W82-04370 5D

Aquacultural Approaches to Recycling of Dissolved Nutrients in Secondarily Treated Domestic Wastewaters--I. Nutrient Uptake and Release by Artificial Food Chains,
W82-04371 5D

AQUATIC ENVIRONMENT
Biota and Biological Principles of the Aquatic Environment.
W82-04499 5C

Pesticides in the Aquatic Environment,
W82-04727 5C

AQUATIC LIFE
The Effects of Sedimentation on Aquatic Life of the Kankakee River, Phase II: Quantitative Studies and Threatened, Endangered, and Rare Species,
W82-04389 5C

AQUATIC PLANTS
Accumulation and Depuration of Metals by Duckweed (Lemna Perpusilla),
W82-04479 5B

Microbial Ecology of River Deposits in the Rivers Kennet and Thames at Reading, England,
W82-04688 5C

AQUIFER CHARACTERISTICS
Ground-Water Conditions in the Upper Virgin River and Kanab Creek Basins Area, Utah, with Emphasis on the Navajo Sandstone,
W82-04486 6D

Maps Showing Ground-Water Conditions in the Bill Williams Area, Mohave, Yavapai, and Yuma Counties, Arizona--1980,
W82-04488 7C

Thickness, Percent Sand, and Configuration of Shallow Hydrogeologic Units in the Powder River Basin, Montana and Wyoming,
W82-04501 7C

Preliminary Data from Arbuckle Test Wells, Miami, Douglas, Saline, and Labette Counties, Kansas,
W82-04512 7C

AQUIFER SYSTEMS
Two-Dimensional Ground-Water Flow Model of the Cretaceous Aquifer System of Lee County and Vicinity, Mississippi,
W82-04492 2F

AQUIFERS
The Response of Groundwater to Artificial Recharge Schemes,
W82-04337 4B

Ground-Water Levels in Arkansas, Spring 1981,
W82-04489 7C

Potentiometric Surface of the Floridan Aquifer in Central Sumter County, Florida, May 1981,
W82-04507 7C

Digital-Model Simulation of the Toppenish Alluvial Aquifer, Yakima Indian Reservation, Washington,
W82-04514 2A

Survey of Selected Organic Compounds in Aquifers of New York State Excluding Long Island,
W82-04520 5B

Theory for Aquifer Test Analysis in Fractured Rock Under Linear (Nonradial) Flow Conditions,
W82-04676 2F

A Model of Hydrothermal Convection in an Aquifer,
W82-04744 1A

ARID ZONE HYDROLOGY
Development of Federal Reserve Rights,
W82-04446 6E

ARIZONA
Reconstructed Stream Flow for the Salt and Verde Rivers from Tree-Ring Data,
W82-04340 2E

The Use of Landsat Imagery in Ground Water Exploration,
W82-04436 7B

Maps Showing Ground-Water Conditions in the Bill Williams Area, Mohave, Yavapai, and Yuma Counties, Arizona--1980,
W82-04488 7C

The Disastrous Southern California and Central Arizona Floods, Flash Floods, and Mudslides of February 1980.
W82-04632 2E

ARKANSAS
Ground-Water Levels in Arkansas, Spring 1981,
W82-04489 7C

Water Resources Data for Arkansas, Water Year 1980.
W82-04503 7C

AROMATIC COMPOUNDS
Biogenic and Abiogenic Polynuclear Aromatic Hydrocarbons in Sediments from Two Remote Adirondack Lakes,
W82-04293 5B

ARTESIAN PRESSURE
Ground-Water Flow Systems and Stability of a Slope,
W82-04677 2J

ARTIFICIAL RECHARGE
The Response of Groundwater to Artificial Recharge Schemes,
W82-04337 4B

ATCHAFALAYA RIVER
Will New Orleans Miss The Mississippi,
W82-04274 4A

ATLANTA
Detention Basins--An Urban Experience,
W82-04332 4A

ATMOSPHERIC WATER
Remote Sensing of Atmospheric Water Content from Satellite Microwave Radiometer (SAMIR) on Bhaskara,
W82-04647 7B

ATOLLS
A Ground Water Resources Study Of A Pacific Ocean Atoll--Tarawa, Gilbert Islands,
W82-04254 2F

AUBURN DAM
Auburn Dam: A Case Study of Water Policy and Economics,
W82-04260 6B

AUTOMATION
American Hoechst Upgrades a Treatment System Through Automation,
W82-04354 5D

A New Method for Sampling Snow Melt and Rainfall in Forests,
W82-04435 7B

Automatic Measuring Station for Continuous Monitoring of Rivers,
W82-04569 5A

Water Quality Monitoring System in Niedersachsen - Application of Automatic Stations for Control and Monitoring of Water Quality,
W82-04575 7B

Utilization of Data from Automatic Water Quality Monitoring Stations in Finland,
W82-04585 7B

Continuous Water Quality Monitoring System Using Telemetry in the City of Osaka,
W82-04590 5A

Automatic Collection and Transmission of Data for the Federal Waterway Authority.
W82-04596 7A

Control and Automation in Wastewater Treatment - Advances, Unsolved Problems and Challenges,
W82-04597 5D

Automatic Operation of a Freeze-Thawing and Dewatering Plant for Sewage Sludges,
W82-04599 5D

Application Examples of and Operating Experiences with the Use of Process Computers in Sewage Treatment Plants,
W82-04600 5D

Experience with Computer Control of Wastewater Treatment Processes at Los Angeles and Other Communities,
W82-04609 5D

Automatic Control of Solids Retention Time and Dissolved Oxygen in the Activated Sludge Process,
W82-04610 5D

AVAILABLE WATER
Water-Resources Investigations of the U.S. Geological Survey in Kansas--Fiscal Year 1979 and 1980,
W82-04510 7C

BACKWASH
Pulsed-Bed Technique Can Cut Treatment Stages,
W82-04613 5D

BACTERIA
Metabolic Responses of Aquatic Bacterial Populations to Selected Insecticides,
W82-04257 5C

Survival and Heterotrophic Activities of Fraser River and Strait of Georgia Bacterioplankton Within the Fraser River Plume,
W82-04291 2L

Density Levels of Pathogenic Organisms in Municipal Wastewater Sludge - A Literature Review,
W82-04400 5E

Sewage Sludge Pathogen Transport Model Project,
W82-04403 5A

Development of the Fecal Streptococcus Group and Its Individual Species as Water Quality Indicators,
W82-04416 5B

Membrane Filter Method for Enumeration of Acinetobacter Calcoaceticus from Environmental Waters,
W82-04453 5A

Evidence for Coexistence of Two Distinct Functional Groups of Sulfate-Reducing Bacteria in Salt Marsh Sediment,
W82-04464 2L

Contribution of Particle-Bound Bacteria to Total Microheterotrophic Activity in Five Ponds and Two Marshes,
W82-04467 2H

Influence of Diluents, Media, and Membrane Filters on Detection of Injured Waterborne Coliform Bacteria,
W82-04469 5A

Nitrifying Population Densities and Inhibition of Ammonium Oxidation in Natural and Sewage-Enriched Cypress Swamps,
W82-04556 5C

BACTERIAL ANALYSIS
Evaluating Mediums and Plating Techniques for Enumerating Bacteria in Water Distribution Systems,
W82-04277 5A

Responses of Bacteria to the Presence of Carbaryl in Water. II. Pure Culture vs. Mixed Culture Response,
W82-04341 5C

Response of Bacteria to the Presence of Carbaryl in Water. I. Response of Bacterial Indicators Vs. Response of Pathogenic Bacterial Species,
W82-04342 5C

Membrane Filter Method for Enumeration of Acinetobacter Calcoaceticus from Environmental Waters,
W82-04453 5A

Enterotoxigenic Bacteria in Food and Water from an Ethiopian Community,
W82-04463 5A

Microbiology of Anaerobic Digestors for Wastewater Purification. (Microbiologie des Digesteurs Anaerobies de l'Epuration des eaux Residuaires),
W82-04544 5D

Some Effects of Land Use on Bacteriological Water Quality in a Recreational Lake,
W82-04567 5B

BALDERHEAD DAM
Design of Filters for Clay Cores of Dams,

LANDSAT
The Use of Landsat Imagery in Ground Water Exploration,
W82-04436 7B

Soil Conservation Service Runoff Curve Number Estimates from Landsat Data,
W82-04438 7B

Ridge Regression Techniques Applied to Landsat Investigation of Water Quality in Lake Okeechobee,
W82-04440 2H

LAS VEGAS SE QUADRANGLE
Flood and Related Debris Flow Hazards Map, Las Vegas SE Quadrangle,
W82-04490 7C

LAWNS
Deterministic Models for Predicting Residential Water Consumption,
W82-04352 6D

LEACHATES
A Finite Element Model for the Migration of Leachate from a Sanitary Landfill in Long Island, New York - Part I: Theory,
W82-04434 5B

LEACHING
Attenuation of Polybrominated Biphenyls and Hexachlorobenzene by Earth Materials,
W82-04620 5B

LEAD
The Scientific Basis for Control of Lead in Drinking Water by Water Treatment,
W82-04301 5F

LEAKAGE
Leak Detection--Histories,
W82-04363 3D

Leak Detection Programs Recover Revenues,
W82-04375 3D

LEAVES
Comparison of Pressure Chamber and Psychrometer Estimates of Leaf Water Potential in Rice,
W82-04541 2I

LEE COUNTY
Two-Dimensional Ground-Water Flow Model of the Cretaceous Aquifer System of Lee County and Vicinity, Mississippi,
W82-04492 2F

LEGAL ASPECTS
The Winters Decision and Indian Water Rights--A Mystery Reexamined,
W82-04410 6E

Experiences with EEC Guideline 75/440 on the Quality of Surface Waters for Drinking Water Production in the Member States (Erfahrungen mit der EG Richtlinie 75/440 Uber die Qualitat von Oberflachenwasser fur die Trinkwassergewinnung in den Mitgliedstaaten).
W82-04547 6E

A Manual for Development of Small Scale Hydroelectric Projects by Public Entities.
W82-04634 6E

Note, Water for Oil Shale: Framework for the Legal Issues,
W82-04681 6E

Covering Distribution Storage, Panel Discussion: State of the Art,
W82-04700 6E

Auctions and Alternative Procedures for Allocating Pollution Rights,
W82-04746 6E

LIME
Lime Softening Sludge Treatment and Disposal.
W82-04276 5E

LIMESTONE AQUIFERS
Carbonate Geochemistry of Vadose Water Recharging Limestone Aquifers,
W82-04526 2F

LIMNOLOGY
Simulation and Verification of Lake Ontario's Mean State,
W82-04570 2H

Limnological Characteristics of Eutrophic Lake Istokpoga, Florida,
W82-04719 2H

LININGS
Covering Bottom Sediments as a Lake Restoration Technique,
W82-04421 5G

LIPIDS
Effect of Water Pollutants and Other Chemicals Upon the Activity of Lipase in Vitro,
W82-04462 5C

LITTER
Organic Carbon Flow in a Swamp-Stream Ecosystem,
W82-04564 5B

LITTORAL ENVIRONMENT
Horizontal Distribution and Flux of Phosphorus in Fish Lake, Wisconsin,
W82-04484 2H

LOANS
The Financing of Private Small Scale Hydroelectric Projects.
W82-04633 6B

LOCAL GIVERNMENTS
A Manual for Development of Small Scale Hydroelectric Projects by Public Entities.
W82-04634 6E

LONG ISLAND
A Finite Element Model for the Migration of Leachate from a Sanitary Landfill in Long Island, New York - Part I: Theory,
W82-04434 5B

LOS ANGELES
Experience with Computer Control of Wastewater Treatment Processes at Los Angeles and Other Communities,
W82-04609 5D

LOUISIANA
Use of Twin Wells and Water-Source Heat Pumps for Energy Conservation in Louisiana,
W82-04387 8B

Water Resources Data for Louisiana, Water Year 1981--Volume 3. Coastal Louisiana.
W82-04523 7C

LOUISVILLE
Developing an Effective Maintenance Program Part A: Evaluation,
W82-04447 5D

LOW FLOW
Estimation of Extreme Low Flows for Pumped Storage Reservoir Design,
W82-04334 2E

MACROPHYTES
The Restoration of Vegetation in Lakes in the Poda Locality near Burgas After Discharging of Biologically Purified Waste Waters (Vuzstanoviavane na Radtitelnata Pokrivka v Subiratelnite Ezera v Mestnosstta Poda Krai Burgas Sled Puskaneto na Biologichno Prechisteni Otpaduchni Vodi v Tiakh),
W82-04476 5C

MACROPOROUS RESINS
Combination of Macroporous Resins and Activated Carbon in Advanced Wastewater Treatment. (Kombination von Makroporosen Adsorberharzen mit Aktivkohle zur Weitergehenden Abwasserreinigung),
W82-04284 5D

MAINE
The Ecological Significance of a Stunted White Perch Population in an Eutrophic Maine Pond,
W82-04418 5C

MAINTENANCE
Developing an Effective Maintenance Program Part A: Evaluation,
W82-04447 5D

Year-Round Distribution System Maintenance,
W82-04699 5F

MANAGEMENT PLANNING
Decisions Under Violation of Regression Normality,
W82-04264 7C

Environmental Threshold Functions for User Oriented Resource Planning and Management,
W82-04289 6B

MANCHESTER
Experiences with Floating Reservoir Covers at the Manchester Water Works,
W82-04697 5G

MAPPING
Soil Conservation Service Runoff Curve Number Estimates from Landsat Data,
W82-04438 7B

LIBRARY U. OF I. - URBANA-CHAMPAIGN

MAPPING

Detection and Mapping of Insoluble Sinking Pollutants,
W82-04619 5A

Usefulness of Monthly Rainfall Normals in Agroclimatic Mapping,
W82-04668 2B

MAPS
Maps Showing Ground-Water Conditions in the Bill Williams Area, Mohave, Yavapai, and Yuma Counties, Arizona--1980,
W82-04488 7C

Flood and Related Debris Flow Hazards Map, Las Vegas SE Quadrangle,
W82-04490 7C

Thickness, Percent Sand, and Configuration of Shallow Hydrogeologic Units in the Powder River Basin, Montana and Wyoming,
W82-04501 7C

Dissolved-Solids Concentrations of Ground Water in the Sacramento Valley, California,
W82-04502 7C

Potentiometric Surface of the Floridan Aquifer in Central Sumter County, Florida, May 1981,
W82-04507 7C

MARGINAL COSTS
Marginal Cost and Seasonal Pricing of Water Service,
W82-04273 6C

On the Marginal Cost of Wastewater Services,
W82-04376 6C

MARINE BACTERIA
Synthesis and Degradation of Carbohydrates in the Marine Planktonic Community of Eutrophic Waters (Synthese et Degradation des Composes Glucidiques au sein de la Commaunaute Planctonique en Zone Marine Eutrophe),
W82-04672 5B

MARKETING
Production Engineering and Marketing Analysis of the Rotating Disk Evaporator,
W82-04405 5D

MARSH PLANTS
A Method for Determining Stress in Wetland Plant Communities Following an Oil Spill,
W82-04548 5C

MARSHES
Contribution of Particle-Bound Bacteria to Total Microheterotrophic Activity in Five Ponds and Two Marshes,
W82-04467 2H

MASSACHUSETTS
Digital Models of Ground-Water Flow in the Cape Cod Aquifer System, Massachusetts,
W82-04487 2F

Massachusetts Water Supply Priorities,
W82-04698 6D

MATHEMATICAL EQUATIONS
Young's Inequality for Three-Dimensional Flows,
W82-04267 2A

Simple Equations for Hooghoudt Equivalent Depth,
W82-04271 4A

MATHEMATICAL MODELS
Decisions Under Violation of Regression Normality,
W82-04264 7C

Delayed Drainage in a Stream-Aquifer System,
W82-04268 2F

The Seepage Flow Through a Free Boundary Aquifer into a River,
W82-04305 2F

Relative Runoff by Curve Number Nomograph,
W82-04307 2A

Dimensionless Stream Advance in Sloping Borders,
W82-04308 3F

Reservoir Sedimentation with Random Deposits,
W82-04443 2J

Analysis of Detention Basin Systems,
W82-04444 2A

A Numerical Linked Model for the Prediction of the Decline of Groundwater Mounds Developed Under Recharge,
W82-04481 2F

Waste Water Treatment Plant Reliability - Engineering Design for Failure and Economic Gain,
W82-04611 5D

Constituents of Highway Runoff; Volume III, Predictive Procedure for Determining Pollution Characteristics in Highway Runoff,
W82-04629 5B

Evaluation of a Chimney Drain Design in an Earthfill Dam,
W82-04675 8D

Modelling Evaporation from Reservoirs,
W82-04722 2D

MATHEMATICAL STUDIES
Dimensionless Stream Advance in Sloping Borders,
W82-04308 3F

The Importance of the Solids Content of the Sludge in Anaerobic Alkaline Digestion (Die Bedeutung des Feststoffgehalts bei der Schlammfaulung),
W82-04549 5D

Application of the Area of Review Concept,
W82-04674 6E

Theory for Aquifer Test Analysis in Fractured Rock Under Linear (Nonradial) Flow Conditions,
W82-04676 2F

MEADOWS
Application of the Wastewater Effluent of a Rural Community to a Mountain Meadow,
W82-04705 5E

MEASURING INSRUMENTS
Continuous Measurement of Organic Solvents in Air and Water (Kontinuierliche Messung Organischer Losemittel in Luft und Wasser),
W82-04579 5A

MEASURING INSTRUMENTS
Electromagnetic Measurements of Tidal Transports in Estuaries,
W82-04296 7B

Ichthyoplankton Samplers for Simultaneous Replicate Samples at Surface and Bottom,
W82-04297 7B

A New Method for Sampling Snow Melt and Rainfall in Forests,
W82-04435 7B

Evaluation of Instruments for Continuous Activated Sludge Monitoring,
W82-04594 5D

MEAT PROCESSING INDUSTRY
Laboratory Experiments on the Physico-Chemical Treatment of Meat Processing Effluents,
W82-04532 5D

MECHANICAL FAILURE
Bank Failure and Erosion on the Ohio River,
W82-04473 2J

MEDFIELD
Vacuum Filtration of Septage,
W82-04710 5D

MEMBRANE PROCESSES
Membrane Filter Method for Enumeration of Acinetobacter Calcoaceticus from Environmental Waters,
W82-04453 5A

METAL-FINISHING WASTES
Chrysler Upgrades Oily Wastes Treatment in Kokomo,
W82-04285 5D

American Hoechst Upgrades a Treatment System Through Automation,
W82-04354 5D

Demonstration of Zinc Cyanide Recovery Using Reverse Osmosis and Evaporation,

LIBRARY U. OF I. - URBANA-CHAMPAIGN

REVIEWS
Recent Developments in and Application of Automation and Monitoring in Water Mangement,
W82-04593 7B

RHINE RIVER
Cytogenetic Effects on the Eastern Mudminnow, Umbra Pygmaea, Exposed to Ethyl Methanesulfonate, Benzo(a)Pyrene, and River Water,
W82-04480 5C

RHODE ISLAND
A Municipal Water Supply Investment Problem in Rhode-Island,
W82-04740 6D

RHODE RIVER ESTUARY
Nutrient Mass Balances for the Watershed, Headwaters Intertidal Zone, and Basin of the Rhode River Estuary,
W82-04330 2L

RICE
Comparison of Pressure Chamber and Psychrometer Estimates of Leaf Water Potential in Rice,
W82-04541 2I

Use of Modified Blaney and Criddle Formula for Estimating Water Requirements,
W82-04667 2D

Note on Puddling Effects on Water Flow Through Soils,
W82-04671 2G

RILL EROSION
How Rain Intensity Affects Interrill Erosion,
W82-04537 2J

RISKS
The Design of Encroachments on Flood Plains Using Risk Analysis,
W82-04631 8A

RIVER BASIN DEVELOPMENT
Water Resources Appraisal for Hydroelectric Licensing: Sevier Lake Basin, Utah.
W82-04636 6D

RIVER BASINS
Forecasting Changes of Water Resources in Large Rivers Following Land Drainage,
W82-04721 2A

RIVER BEDS
Transverse Bed Slope in Alluvial Channel Bends,
W82-04366 2J

Anastomosed River Deposits: Modern and Ancient Examples in Alberta, Canada,
W82-04531 2J

Mathematical Simulation of Sediment Movement in Streams,
W82-04650 2J

Resistance Equation for Large-Scale Roughness,
W82-04696 2E

RIVER FLOW
The Effects of Sedimentation on Aquatic Life of the Kankakee River, Phase II: Quantitative Studies and Threatened, Endangered, and Rare Species,
W82-04389 5C

RIVER SYSTEMS
Data Acquisition for River Management,
W82-04601 7A

RIVER WATER
The Neckar as a Source of Process and Reserve Water (Der Neckar als Lifeferant von Betriebs- und Reservewasser),
W82-04546 5F

RIVERS
A Data Acquisition System for Recording and Processing River Quality Monitoring Data,
W82-04592 7A

Selected Trace Metals in the Upper St. Johns River and Their Land Use Relationships,
W82-04718 5B

ROAD CONSTRUCTION
Roads in Water-Procuring Regions - Water Pollution Control and Safeguarding of Water Supply, Exemplified by the Stuttgart-Singen Autobahn (Strassen in Wassergewinnungsgebieten-gewasserschutz und Sicherstellung der Wasserversorgung am Beispiel der Autobahn A 81 Stuttgart-Singen),
W82-04551 4B

ROADS
Constituents of Highway Runoff; Volume I, State-of-the-Art Report,
W82-04627 4C

ROOTS
Spacing and Transpiration of Various Sized Clumps of a Desert Grass, Hilaria Rigida,
W82-04295 2D

Analysis of the Components of Area Growth of Bean Root Systems,
W82-04715 2I

ROTATING DISK EVAPORATORS
Production Engineering and Marketing Analysis of the Rotating Disk Evaporator,
W82-04405 5D

RUNOFF
Water Quality Patterns During A Storm On A Mall Parking Lot,
W82-04252 5B

Relation Between Curve Number and Runoff Coefficient,
W82-04266 2A

Constituents of Highway Runoff; Volume II, Procedural Manual for Monitoring of Highway Runoff,
W82-04628 5A

Constituents of Highway Runoff; Volume III, Predictive Procedure for Determining Pollution Characteristics in Highway Runoff,
W82-04629 5B

Constituents of Highway Runoff; Volume V, Highway Runoff Data Storage Program and Computer User's Manual,
W82-04630 5B

Constituents of Highway Runoff; Volume IV, Characteristics of Highway Runoff from Operating Highways. Research Report,
W82-04637 5B

RUNOFF CYCLE
Man-Made Storage of Water Resources-A Liability to the Ocean Environment. Part I,
W82-04749 6G

RUNOFF FORECASTING
Soil Conservation Service Runoff Curve Number Estimates from Landsat Data,
W82-04438 7B

Comparison of Models for Forecasting Snowmelt Runoff Volumes,
W82-04452 2A

RUNOFF RATES
Severe Snowmelt Runoff in North-East England and Its Implications,
W82-04648 2E

RURAL AREAS
Rural Power Schemes in Pakistan,
W82-04328 8A

Experiments in Improving Rural Water Supplies,
W82-04350 5F

Slow-Sand Test-Beds Help Refine Design,
W82-04614 5F

SACRAMENTO
Auburn Dam: A Case Study of Water Policy and Economics,
W82-04260 6B

SACRAMENTO VALLEY
Dissolved-Solids Concentrations of Ground Water in the Sacramento Valley, California,
W82-04502 7C

SAGAMORE LAKE
Biogenic and Abiogenic Polynuclear Aromatic Hydrocarbons in Sediments from Two Remote Adirondack Lakes,
W82-04293 5B

SALAMANDERS
Toxicity of Nitrite to Larvae of the Salamander Ambystoma Texanum,
W82-04529 5C

SALINE-FRESHWATER INTERFACES
Oregon Coastal Salt Marsh Upper Limits and Tidal Datums,
W82-04312 2L

Evaluation of Electromagnetic Terrain Conductivity Measurements for Detection and Mapping of Salt-water interfaces in Coastal Aquifers.
W82-04412 5A

SALINE SOILS
Irrigation, Crop Yield and Drainage at the Vaalharts Irrigation Scheme: 3. The Influence of Salinization Above a Shallow Ground Water Table on the Yield of Wheat and Other Crops (In Afrikaans),
W82-04359 2G

SALINE WATER
The Chemistry of Saline Water Chlorination,
W82-04729 3C

SALINE WATER INTRUSION
Will New Orleans Miss The Mississippi,
W82-04274 4A

Irrigation, Crop Yield and Drainage at the Vaalharts Irrigation Scheme: 3. The Influence of Salinization Above a Shallow Ground Water Table on the Yield of Wheat and Other Crops (In Afrikaans),
W82-04359 2G

Salinity Intrusion in Estuaries,
W82-04574 2L

Dispersion Coefficients in Estuaries,
W82-04684 5B

SALINITY
Seasonal Changes in the Depth Distributions of Interstitial Salinities in the Fraser River Estuary, British Columbia,
W82-04717 2L

SALT DOMES
Isotope Geochemistry of Water in Gulf Coast Salt Domes,
W82-04742 2K

SALT MARSHES
Oregon Coastal Salt Marsh Upper Limits and Tidal Datums,
W82-04312 2L

Evidence for Coexistence of Two Distinct Functional Groups of Sulfate-Reducing Bacteria in Salt Marsh Sediment,
W82-04464 2L

Sheet Flow in a Salt-Marsh Basin, North Inlet, South Carolina,
W82-04716 2L

SALT RIVER
Reconstructed Stream Flow for the Salt and Verde Rivers from Tree-Ring Data,
W82-04340 2E

SAMPLE PRESERVATION
The Effect of Storage by Freezing on Dissolved Inorganic Phosphate, Nitrate and Reactive Silicate for Samples from Coastal and Estuarine Waters,
W82-04660 5A

SAMPLING
Ichthyoplankton Samplers for Simultaneous Replicate Samples at Surface and Bottom,
W82-04297 7B

A Probe Method for Soil Water Sampling and Subsurface Measurements,
W82-04325 7B

Manual Groundwater Sampling device (Vorrichtung Zur Manuellen Wasserprobenentnahme Aus Grundwassermessstellen),
W82-04582 7B

SAND FILTERS
Slow-Sand Test-Beds Help Refine Design,
W82-04614 5F

SANGAMON RIVER
Evaluating Stream Standard Violations Using a Water Quality Data Base,
W82-04286 5A

SAUDI ARABIA
Jeddah IV Seawater Desalination and Power Plant in Operation in Saudi Arabia (Meerwasserentsalzungs und Kraftanlage Jeddah IV in Saudi - Arabien in Betrieb),
W82-04581 3A

SCALING
The Siderite Model of The Formation of Corrosion-Resistant Scales,
W82-04270 5F

SCOUR
The Vortex Scour Mechanism at Bridge Piers,
W82-04642 8B

SEA WATER
Effects of Phenol on Oxygen Consumption in The Whelk, Bullia Digitalis (Dillwyn),
W82-04262 5C

SEASONAL EFFECTS
Seasonal Variations in Primary Production in Surface Waters of the Saguenay River (Variations Saisonnieres de la Production Primaire dans les eaux de Surface de la Riviere du Saguenay),
W82-04678 5C

SEASONAL VARIATION
Marginal Cost and Seasonal Pricing of Water Service,
W82-04273 6C

Secular Changes in Annual and Seasonal Great Lakes Precipitation, 1854-1979, and Their Implications for Great Lakes Water Resource Studies,
W82-04431 2B

Regional Hydrologic Models for Climatology: An Application to Three Wisconsin Watersheds,
W82-04483 2A

Seasonality of Flooding and the Assessment of Seasonal Flood Risk,
W82-04646 2E

Seasonal Changes in the Depth Distributions of Interstitial Salinities in the Fraser River Estuary, British Columbia,
W82-04717 2L

SEAWATER
Determination of Trace Elements in Seawater by Neutron Activation Analysis and Electrochemical Separation,
W82-04530 5A

SECONDARY WASTEWATER TREATMENT
Relative Effects on Stream Biota of Chlorine and Ammonia Occurring in Secondary Sewage,
W82-04409 5C

Parallel Evaluation of Air- and Oxygen-Activated Sludge,
W82-04624 5D

SEDIMENT CONTROL
Approximate Sizing of Reservoirs for Detention Time,
W82-04315 8A

SEDIMENT COVERS
Covering Bottom Sediments as a Lake Restoration Technique,
W82-04421 5G

SEDIMENT DISCHARGE
Reservoir Sedimentation with Random Deposits,
W82-04443 2J

SEDIMENT SAMPLER
A Probe Method for Soil Water Sampling and Subsurface Measurements,
W82-04325 7B

Collapsible-Bag Suspended-Sediment Sampler,
W82-04745 7B

SEDIMENT TRANSPORT
Transverse Bed Slope in Alluvial Channel Bends,
W82-04366 2J

Incipient Motion of Sand Particles on Side Slopes,
W82-04368 8D

Nutrient and Heavy Metal Transport Capabilities of Sediment in the Southwestern United States,
W82-04437 2J

How Rain Intensity Affects Interrill Erosion,
W82-04537 2J

A Kinetic Model for Surface Mine Sediment Yield,
W82-04552 2J

Mathematical Simulation of Sediment Movement in Streams,
W82-04650 2J

SEDIMENTATION
The Effects of Sedimentation on Aquatic Life of the Kankakee River, Phase II: Quantitative Studies and Threatened, Endangered, and Rare Species,
W82-04389 5C

Reservoir Sedimentation with Random Deposits,
W82-04443 2J

Reservoir Sedimentation and Its Causes in Illinois,
W82-04450 2J

Erosion and Sedimentation in the Kenai River, Alaska,
W82-04495 2J

Anastomosed River Deposits: Modern and Ancient Examples in Alberta, Canada,
W82-04531 2J

Addition of Radiocarbon to the Mixed-Layers of Two Small Lakes: Primary Production, Gas Exchange, Sedimentation and Carbon Budget,
W82-04730 2H

SEDIMENTATION BASINS
Approximate Sizing of Reservoirs for Detention Time,
W82-04315 8A

Ponding Surface Drainage Water for Sediment and Phosphorus Removal,
W82-04358 4D

SEDIMENTATION RATES
Sedimentation Rates and Depositional Processes in Lake Superior from Pb210 Geochronology,
W82-04380 2J

SEDIMENTS
Biogenic and Abiogenic Polynuclear Aromatic Hydrocarbons in Sediments from Two Remote Adirondack Lakes,
W82-04293 5B

Covering Bottom Sediments as a Lake Restoration Technique,
W82-04421 5G

Evidence for Coexistence of Two Distinct Functional Groups of Sulfate-Reducing Bacteria in Salt Marsh Sediment,
W82-04464 2L

Anastomosed River Deposits: Modern and Ancient Examples in Alberta, Canada,
W82-04531 2J

Heavy Metal Content in Sediments of Lakes in Southern Bavaria as a Sign of Long-Term Environmental Impact (Schwermetallgehalte in Sedimenten Sudbayerischer Seen als Indikatoren Langfristiger Umweltbelastung),
W82-04550 5B

Determination of Characteristic Values for Physical and Chemical Lake Sediment Parameters,
W82-04586 2H

Seasonal Changes in the Depth Distributions of Interstitial Salinities in the Fraser River Estuary, British Columbia,
W82-04717 2L

Distribution of Clay Minerals and Their Diagenesis in the Sediments of Lake Edku,
W82-04748 2J

SEEPAGE CONTROL
Wet Disposal of Fossil Plant Waste: Case History,
W82-04385 5E

SEMIARID LANDS
Blaney-Criddle Coefficients for Western Turf Grasses,
W82-04310 2D

Storm Runoff Analyses on Three Semi-Arid Catchments,
W82-04339 2A

SEPARATION TECHNIQUES
Chrysler Upgrades Oily Wastes Treatment in Kokomo,
W82-04285 5D

Treatment of Noncyanide Electroplating Cadmium Wastewater by Reverse Osmosis,
W82-04664 5D

LIBRARY U. OF I., URBANA CHAMPAIGN

SEPTIC TANKS
Operational Performance of an RBC Unit in Conjunction with a Septic Tank,
W82-04355 5D

SEPTIC WASTEWATER
Vacuum Filtration of Septage,
W82-04710 5D

SETTLING VELOCITY
Variation of Sludge Volume Index with Activated Sludge Characteristics,
W82-04555 5D

SEVERN ESTUARY
A Suspended Sediment Front in the Severn Estuary,
W82-04639 2L

SEVERN-TRENT WATER AUTHORITY
A Data Acquisition System for Recording and Processing River Quality Monitoring Data,
W82-04592 7A

The Seven-Trent Studies of Industrial Water Use,
W82-04686 6D

SEVIER LAKE BASIN
Water Resources Appraisal for Hydroelectric Licensing: Sevier Lake Basin, Utah.
W82-04636 6D

SEWER INFILTRATION
Hourly Diurnal Flow Variations in Publicly-Owned Wastewater Treatment Facilities,
W82-04402 5D

SEWER SYSTEMS
Hourly Diurnal Flow Variations in Publicly-Owned Wastewater Treatment Facilities,
W82-04402 5D

Storm Sewer Flow Computations,
W82-04640 7B

Adopting Sewers,
W82-04655 8A

SHELLFISH
Effects of Phenol on Oxygen Consumption in The Whelk, Bullia Digitalis (Dillwyn),
W82-04262 5C

SIMULATION
Determination of Effective Well Block Radii for Numerical Reservoir Simulations,
W82-04732 6A

SITE SELECTION
Environmental Threshold Functions for User Oriented Resource Planning and Management,
W82-04289 6B

SLOPE DEGRADATION
Transverse Bed Slope in Alluvial Channel Bends,
W82-04366 2J

SLOPE STABILITY
Incipient Motion of Sand Particles on Side Slopes,
W82-04368 8D

Ground-Water Flow Systems and Stability of a Slope,
W82-04677 2J

SLOPES
Two-Dimensional Soil Moisture Flow in a Sloping Rectangular Region: Experimental and Numerical Studies,
W82-04333 2A

SLUDGE
Parasites in Southern Sludges and Disinfection by Standard Sludge Treatment,
W82-04408 5B

Proportions of Several Elements Found in Sewage Effluent and Sludge from Several Municipalities in West Virginia,
W82-04465 5B

SLUDGE CONDITIONING
Automatic Control of Sludge Conditioning and Vacuum Filtration,
W82-04589 5E

SLUDGE DISPOSAL
Lime Softening Sludge Treatment and Disposal.
W82-04276 5E

Sludge Disposal by Combustion Offers Potential Energy Source,
W82-04329 5E

Sewage Sludge Pathogen Transport Model Project,
W82-04403 5A

Automatic Control of the Sewage Sludge Pyrolysis Process in Multiple Hearth Furnace,
W82-04587 5E

Automatic Control of Sludge Conditioning and Vacuum Filtration,
W82-04589 5E

Densification of Paper Mill Sludge Materials,
W82-04694 5E

SLUDGE DRYING
American Hoechst Upgrades a Treatment System Through Automation,
W82-04354 5D

Density Levels of Pathogenic Organisms in Municipal Wastewater Sludge - A Literature Review,
W82-04400 5E

Automatic Operation of a Freeze-Thawing and Dewatering Plant for Sewage Sludges,
W82-04599 5D

Air Drying Liquid Anaerobically Digested Sludge in Earthen Drying Basins,
W82-04711 5D

SLUDGE THICKENING
Automatic Operation of a Freeze-Thawing and Dewatering Plant for Sewage Sludges,
W82-04599 5D

SLUDGE UTILIZATION
Air Drying Liquid Anaerobically Digested Sludge in Earthen Drying Basins,
W82-04711 5D

SLUDGE VOLUME INDEX
Variation of Sludge Volume Index with Activated Sludge Characteristics,
W82-04555 5D

SLUSH
Convection Patterns in a Pond,
W82-04461 2C

SNOW
Acid Snow in the Canadian High Arctic,
W82-04542 2C

SNOWMELT
Problems of Modelling a High Mountainous Drainage Basin with Predominant Snow Yields,
W82-04303 2A

Elevation: A Major Influence on the Hydrology of New Hampshire and Vermont, USA,
W82-04304 2E

A New Method for Sampling Snow Melt and Rainfall in Forests,
W82-04435 7B

Comparison of Models for Forecasting Snowmelt Runoff Volumes,
W82-04452 2A

Severe Snowmelt Runoff in North-East England and Its Implications,
W82-04648 2E

The Future of Flood Estimation and the Flood Studies Report,
W82-04687 2E

SOCIAL ASPECTS
The Relationship of Accessible Safe Water and Adequate Sanitation to Maternal and Child Health--Looking Forward to the Drinking Water and Sanitation Decade,
W82-04606 6D

SOIL CONTAMINATION
An Integrated Water-Quality Index for Irrigation Use,
W82-04723 5C

SOIL PROFILES
Infiltration into Two-Layered Soil Profiles,
W82-04536 2G

SOIL PROPERTIES
Effect of Surface Sealing on Infiltration,
W82-04362 2G

SOIL WATER
A Probe Method for Soil Water Sampling and Subsurface Measurements,
W82-04325 7B

Two-Dimensional Soil Moisture Flow in a Sloping Rectangular Region: Experimental and Numerical Studies,
W82-04333 2A

Effect of Surface Sealing on Infiltration,
W82-04362 2G

Infiltration into Two-Layered Soil Profiles,
W82-04536 2G

Note on Puddling Effects on Water Flow Through Soils,
W82-04671 2G

Water Movement in Uniform Soils During Constant-Flux Infiltration,
W82-04691 2G

SOIL WATER MOVEMENT
Water Movement Factors Important to the Design and Operation of Subirrigation Systems,
W82-04538 3F

Water Movement in Uniform Soils During Constant-Flux Infiltration,
W82-04691 2G

SOIL-WATER-PLANT RELATIONSHIPS
Effects of Decreased Watering on Crop Yields,
W82-04411 2I

Soil and Water Regimes for Optimum and for Maximum Yields,
W82-04415 3F

Effects of Soil Moisture, Planting Date, and Weeds on Cereal Yields (Effets de l'Humidite du Sol, des Dates de Semis et des Mauvaises Herbes sur le Rendement des Cereales),
W82-04470 2I

Sorghum and Barley in Southern Alberta: Grain Yield Response to Irrigation and Fertilizer,
W82-04471 2I

SOLAR RADIATION
Sunlight Induced Movement of Planktonic Organisms and Their Relationships to Water Movements,
W82-04417 2H

SOLID WASTE DISPOSAL
Wet Disposal of Fossil Plant Waste: Case History,
W82-04385 5E

Automatic Control of the Sewage Sludge Pyrolysis Process in Multiple Hearth Furnace,
W82-04587 5E

SOLIDS CONTACT PROCESSES
Operational Performance of an RBC Unit in Conjunction with a Septic Tank,
W82-04355 5D

SOLUBILITY
Attenuation of Polybrominated Biphenyls and Hexachlorobenzene by Earth Materials,
W82-04620 5B

Influence of an Americium Solid Phase on Americium Concentrations in Solutions,
W82-04720 5B

SOLUTE TRANSPORT
Dispersion Coefficients in Estuaries,
W82-04684 5B

SOLVENTS
Continuous Measurement of Organic Solvents in Air and Water (Kontinuierliche Messung Organischer Losemittel in Luft und Wasser),
W82-04579 5A

SORGHUM
Sorghum and Barley in Southern Alberta: Grain Yield Response to Irrigation and Fertilizer,
W82-04471 2I

SOUTH AFRICA
Effects of Phenol on Oxygen Consumption in The Whelk, Bullia Digitalis (Dillwyn),
W82-04262 5C

Storm Runoff Analyses on Three Semi-Arid Catchments,
W82-04339 2A

A Preliminary Pollution Survey of the Papenkuils River, Port Elizabeth,
W82-04346 5B

Health Aspects of Waters at Public Health Resorts,
W82-04348 5A

Irrigation, Crop Yield and Drainage at the Vaalharts Irrigation Scheme: 3. The Influence of Salinization Above a Shallow Ground Water Table on the Yield of Wheat and Other Crops (In Afrikaans),
W82-04359 2G

SOUTH CAROLINA
Sheet Flow in a Salt-Marsh Basin, North Inlet, South Carolina,
W82-04716 2L

SOUTH PLATTE RIVER
Simulated Interactions Between the Proposed Narrows Reservoir and the Water-Table Aquifer Along the South Platte River, Morgan County, Colorado,
W82-04725 6A

SPATIAL DISTRIBUTION
Depth, Silt and Current: Factors in the Transverse Microdistribution of the Benthos in the Freshwater Estuary of the St. Lawrence (Profondeur, Vase et Courant, Facteurs de Microrepartition Transversale du Benthos dans l'Estuaire d'eau Douce du Saint-Laurent (Quebec),
W82-04472 2L

SPECIES COMPOSITION
Depth, Silt and Current: Factors in the Transverse Microdistribution of the Benthos in the Freshwater Estuary of the St. Lawrence (Profondeur, Vase et Courant, Facteurs de Microrepartition Transversale du Benthos dans l'Estuaire d'eau Douce du Saint-Laurent (Quebec),
W82-04472 2L

SPILLWAY CAPACITY
The Future of Flood Estimation and the Flood Studies Report,
W82-04687 2E

SPILLWAY GATES
Aeration Characteristics of Flow Release Controls on Illinois Waterway Dams,
W82-04388 5G

SPILLWAYS
Analysis of the Hydraulic Jump Within a Diverging Rectangular Channel,
W82-04645 8B

James Bay Spillways and Control Structures,
W82-04692 8A

ST JOHNS RIVER
Selected Trace Metals in the Upper St. Johns River and Their Land Use Relationships,
W82-04718 5B

ST. LAWRENCE ESTUARY
Vertical Mixing and Photosynthetic Capacity of Estuarine Phytoplankton (Melange Vertical et Capacite Photosynthetique du Phytoplancton Estuarien (Estuaire du Saint-Laurent)),
W82-04331 2L

ST LAWRENCE RIVER
Depth, Silt and Current: Factors in the Transverse Microdistribution of the Benthos in the Freshwater Estuary of the St. Lawrence (Profondeur, Vase et Courant, Facteurs de Microrepartition Transversale du Benthos dans l'Estuaire d'eau Douce du Saint-Laurent (Quebec),
W82-04472 2L

STABILIZATION PONDS
The Development of Design Equations for Facultative Waste Stabilization Ponds in Semiarid Areas,
W82-04641 5D

STANDARDS
Evaluating Stream Standard Violations Using a Water Quality Data Base,
W82-04286 5A

STATE JURISDICTION
Recent Developments in Colorado Groundwater Law,
W82-04679 6E

Bubb v. Christensen: The Rights of the Private Landowner Yield to the Rights of the Water Appropriator Under the Colorado Doctrine,
W82-04680 6E

STATISTICAL ANALYSIS
Decisions Under Violation of Regression Normality,
W82-04264 7C

Performance of Activated Sludge Processes: Reliability, Stability and Variability,
W82-04394 5D

A Method for Estimating Peak Water Demand of Multifamily Residences,
W82-04734 6D

STEEL INDUSTRY
Detoxification of Waste Water Containing Cyanides from the Wet-Scrubbing Systems of Steel Mills (Entgiftung Cyanidhaltigen Gichtgaswaschwasser von Hochofen),
W82-04616 5D

STOCHASTIC HYDROLOGY
Comparison of Two Autoregressive Models for Monthly Stream Flow Generation,
W82-04351 2E

STORAGE
The Effect of Storage by Freezing on Dissolved Inorganic Phosphate, Nitrate and Reactive Silicate for Samples from Coastal and Estuarine Waters,
W82-04660 5A

STORAGE CAPACITY
Water Budget Computations for a Shallow--Lake Okeechobee, Florida,
W82-04258 2H

Pumped Outlets for Drainage Systems,
W82-04364 8A

STORM RUNOFF
Relative Runoff by Curve Number Nomograph,
W82-04307 2A

The General Hydrologic System Model,
W82-04314 2A

Storm Runoff Analyses on Three Semi-Arid Catchments,
W82-04339 2A

Areawide Stormwater Pollution Analysis with the Macroscopic Planning (ABMAC) Model,
W82-04393 5B

Thunderstorm in Agriculture and in Forest Management,
W82-04617 2B

Constituents of Highway Runoff; Volume I, State-of-the-Art Report,
W82-04627 4C

Constituents of Highway Runoff; Volume IV, Characteristics of Highway Runoff from Operating Highways. Research Report,
W82-04637 5B

STORM SEWERS
Optimal Design of Urban Storm Water Drainage Systems,
W82-04414 8A

Storm Sewer Flow Computations,
W82-04640 7B

STORM WATER
Areawide Stormwater Pollution Analysis with the Macroscopic Planning (ABMAC) Model,
W82-04393 5B

Development of Improved Stormwater Quality Models,
W82-04559 5B

STORMS
Hydroclimatological Characteristics of Isolated Severe Rainstorms,
W82-04336 2B

STRATIFICATION
Temperatures and Currents in a Stratified Lake: A Two-Dimensional Analysis,
W82-04378 2H

STREAM BANKS
Incipient Motion of Sand Particles on Side Slopes,
W82-04368 8D

STREAM CLASSIFICATION
Watersheds As The Basic Ecosystems: This Conceptual Framework Provides A Basis For A Natural Classification System,
W82-04253 7C

Inertia and Recovery: An Approach to Stream Classification and Stress Evaluation,
W82-04735 6G

STREAM EROSION
Methods for Assessment of Stream-Related Hazards to Highways and Bridges,
W82-04626 8A

LIBRARY U. OF I. - URBANA-CHAMPAIGN

STREAMFLOW
Elevation: A Major Influence on the Hydrology of New Hampshire and Vermont, USA,
W82-04304 2E

Reconstructed Stream Flow for the Salt and Verde Rivers from Tree-Ring Data,
W82-04340 2E

Comparison of Two Autoregressive Models for Monthly Stream Flow Generation,
W82-04351 2E

Search: A Gaged Watershed Inventory,
W82-04433 10B

Mean Annual Streamflow of Selected Drainage Basins in the Coal Area of Southeastern Montana,
W82-04506 5C

Quality of Surface Water in the Coal-Mining Areas of Western Maryland and Adjacent Areas of Pennsylvania and West Virginia from April 1979 to June 1980,
W82-04516 7C

Selected Hydrologic Relationships for Soldier Creek, Northeastern Kansas,
W82-04519 2E

The Development of a Viable Method of Stream Flow Measurement Using the Integrating Float Technique,
W82-04643 7B

STREAMFLOW FORECASTING
A Dimensionless Unit Hydrograph for Urbanizing Catchment Areas,
W82-04683 2A

STREAMFLOW-WATER QUALITY RELATIONS
Hysteresis in Relationships Between Discharge and Water Chemistry in the Fraser River Basin, British Columbia,
W82-04326 2K

STREAMS
Erosion and Sedimentation in the Kenai River, Alaska,
W82-04495 2J

Organic Carbon Flow in a Swamp-Stream Ecosystem,
W82-04564 5B

STRESS
A Stress Function for Evaluating Strategies for Water Quality Management,
W82-04407 5C

A Method for Determining Stress in Wetland Plant Communities Following an Oil Spill,
W82-04548 5C

Application of the Southwell Plot Method to the Inspection and Testing of Buried Flexible Pipes,
W82-04649 8A

Inertia and Recovery: An Approach to Stream Classification and Stress Evaluation,
W82-04735 6G

STRIP MINE WASTES
Topsoil Management of Mined Soils,
W82-04571 4D

STRIP MINES
Modeled Impacts of Surface Coal Mining on Dissolved Solids in the Tongue River, Southeastern Montana,
W82-04494 5G

Quality of Surface Water in the Coal-Mining Areas of Western Maryland and Adjacent Areas of Pennsylvania and West Virginia from April 1979 to June 1980,
W82-04516 7C

A Kinetic Model for Surface Mine Sediment Yield,
W82-04552 2J

Topsoil Management of Mined Soils,
W82-04571 4D

STRUCTURAL GEOLOGY
Preliminary Data from Arbuckle Test Wells, Miami, Douglas, Saline, and Labette Counties, Kansas,
W82-04512 7C

STUTTGART
The Neckar as a Source of Process and Reserve Water (Der Neckar als Lifeferant von Betriebs- und Reservewasser),
W82-04546 5F

SUBLETHAL EFFECTS
A Method for Determining Stress in Wetland Plant Communities Following an Oil Spill,
W82-04548 5C

SUBSTRATES
The Effects of Sedimentation on Aquatic Life of the Kankakee River, Phase II: Quantitative Studies and Threatened, Endangered, and Rare Species,
W82-04389 5C

SUBSURFACE DRAINAGE
Delayed Drainage in a Stream-Aquifer System,
W82-04268 2F

SUBSURFACE IRRIGATION
Water Movement Factors Important to the Design and Operation of Subirrigation Systems,
W82-04538 3F

SUGARCANE
Use of Modified Blaney and Criddle Formula for Estimating Water Requirements,
W82-04667 2D

SULFATES
Evidence for Coexistence of Two Distinct Functional Groups of Sulfate-Reducing Bacteria in Salt Marsh Sediment,
W82-04464 2L

SULFUR
The Biogeochemistry of Sulfur in Two Small Lakes,
W82-04726 2H

SULFUR DIOXIDE
Wastewater Dechlorination State-Of-The-Art Field Survey and Pilot Studies,
W82-04392 5D

SUMPS
Pumped Outlets for Drainage Systems,
W82-04364 8A

SUNFLOWER
Sunflower Yield Vs. Water Deficits in Major Growth Periods,
W82-04361 2I

SURFACE-GROUNDWATER RELATIONS
Effect of Irrigation Pumping on the Ground-Water System in Newton and Jasper Counties, Indiana,
W82-04497 4B

Simulated Hydrologic Effects of Possible Ground-Water and Surface-Water Management Alternatives in and near the Platte River, South-Central Nebraska,
W82-04509 6G

Digital-Model Simulation of the Toppenish Alluvial Aquifer, Yakima Indian Reservation, Washington,
W82-04514 2A

Simulated Interactions Between the Proposed Narrows Reservoir and the Water-Table Aquifer Along the South Platte River, Morgan County, Colorado,
W82-04725 6A

SURFACE RUNOFF
A Kinetic Model for Surface Mine Sediment Yield,
W82-04552 2J

SURFACE SEALING
Effect of Surface Sealing on Infiltration,
W82-04362 2G

SURFACE WATER
Effects of Land Use on Surface-Water Quality in the East Everglades, Dade County, Florida,
W82-04491 5C

Water Resources Data for Arkansas, Water Year 1980.
W82-04503 7C

Hydrologic Reconnaissance of the Beluga, Peters Creek, and Healy Coal Areas, Alaska,
W82-04504 7C

Water Resources Inventory of Connecticut, Part 7, Upper Connecticut River Basin,
W82-04505 2E

Water-Resources Investigations of the U.S. Geological Survey in Kansas--Fiscal Year 1979 and 1980,
W82-04510 7C

Water-Quality Data for Selected Stations in the East Everglades, Florida,
W82-04513 7C

Water Type and Suitability of Oklahoma Surface Waters for Public Supply and Irrigation. Part 1: Arkansas River Mainstem and Verdigris, Neosho, and Illinois River Basins Through 1978,
W82-04518 7C

Water Resources Data for Pennsylvania, Water Year 1980--Volume 1. Delaware River Basin.
W82-04521 7C

Water Resources Data for West Virginia, Water Year 1980. Appendix - Coal Areas.
W82-04522 7C

Water Resources Data for Louisiana, Water Year 1981--Volume 3. Coastal Louisiana.
W82-04523 7C

SURGES
Simulation of Surges After Removal of a Separating Barrier Between Shallower and Deeper Bodies of Water,
W82-04685 8B

SUSPENDED SEDIMENTS
Ridge Regression Techniques Applied to Landsat Investigation of Water Quality in Lake Okeechobee,
W82-04440 2H

A Suspended Sediment Front in the Severn Estuary,
W82-04639 2L

Collapsible-Bag Suspended-Sediment Sampler,
W82-04745 7B

SUSPENDED SOLIDS
The Effects of pH and Suspended Solids in the Removal of Organics from Water and Wastewaters by the Activated Carbon Adsorption Process,
W82-04568 5D

SWAMPS
Organic Carbon Flow in a Swamp-Stream Ecosystem,
W82-04564 5B

SWEDEN
Determination of Characteristic Values for Physical and Chemical Lake Sediment Parameters,
W82-04586 2H

SWIMMING POOLS
Health Aspects of Waters at Public Health Resorts,
W82-04348 5A

SYNOPTIC ANALYSIS
Statistical Forecasting of Heavy Rain and Floods in the River Teesta,
W82-04670 2B

SYNTHETIC ORGANICS
Evaluation and Treatment of Synthetic Organics in Drinking Water Supplies,
W82-04427 5F

TANZANIA
Costing Dar-Es-Salaam's Sanitation Plan,
W82-04603 6C

Tanzania's Master Water Plan Will Miss Decade Goal,
W82-04657 5F

TARAWA
A Ground Water Resources Study Of A Pacific Ocean Atoll--Tarawa, Gilbert Islands,
W82-04254 2F

TASTE
Treating Taste and Odour Problems Using Ozone and Activated Carbon,
W82-04553 5F

TAXONOMY
An Annotated Key to the Identification of Commonly Occurring and Dominant Genera of Algae Observed in the Phytoplankton of the United States,
W82-04524 5C

TEESTA RIVER
Statistical Forecasting of Heavy Rain and Floods in the River Teesta,
W82-04670 2B

TELEMETRY
Telemetric Water Control System of the Artificially Aerated Mosel River,
W82-04598 5G

TELTOW CANAL
Evaluation of Water Quality Data Received by Automatic Control Stations at the Teltow-Canal in Berlin (West),
W82-04607 5A

TEMPERATURE
Estimation of Primary Productivity in Aquatic Systems Using Free Oxygen Measurements,
W82-04256 2H

Temperature Dependency of Biological Denitrification with Organic Materials Addition,
W82-04662 5D

TEMPERATURE EFFECTS
Effect of Temperature on Heterotrophic Glucose Uptake, Mineralization, and Turnover Rates in Lake Sediments,
W82-04466 2H

TERTIARY WASTEWATER TREATMENT
Aquacultural Approaches to Recycling of Dissolved Nutrients in Secondarily Treated Domestic Wastewater--IV. Conclusions, Design and Operational Considerations for Artificial Food Chains,
W82-04369 5D

Aquacultural Approaches to Recycling of Dissolved Nutrients in Secondarily Treated Domestic Wastewaters--III. Uptake of Dissolved Heavy Metals by Artificial Food Chains,
W82-04370 5D

Aquacultural Approaches to Recycling of Dissolved Nutrients in Secondarily Treated Domestic Wastewaters--I. Nutrient Uptake and Release by Artificial Food Chains,
W82-04371 5D

TEST WELLS
Results of Hydrologic Tests and Water-Chemistry Analyses, Wells H-4A, H-4B, and H-4C at the Proposed Waste Isolation Pilot Plant Site, Southeastern New Mexico,
W82-04517 5B

TEXAS
Application of the OECD Eutrophication Modeling Approach to Lake Ray Hubbard, Texas,
W82-04278 5C

TNRIS: A Source for Water-Related Data in Texas.
W82-04651 10B

THAMES RIVER
Requirements for Continuous Automatic Water Quality Monitoring in the Thames Estuary,
W82-04591 2L

Data Acquisition for River Management,
W82-04601 7A

Microbial Ecology of River Deposits in the Rivers Kennet and Thames at Reading, England,
W82-04688 5C

THERMAL POLLUTION
Vertical Round Buoyant Jet in Shallow Water,
W82-04365 7C

Nearfield Performance of River Diffusers,
W82-04561 5B

THERMAL PROPERTIES
The Geothermal Hydrology of Warner Valley, Oregon: A Reconnaissance Study,
W82-04496 1A

Geochemistry of Thermal and Mineral Waters in the Cascade Mountains of Western North America,
W82-04673 2K

THERMAL SPRINGS
Geochemistry of Thermal and Mineral Waters in the Cascade Mountains of Western North America,
W82-04673 2K

THERMAL STRATIFICATION
Winter Temperature Structure in Lake Huron,
W82-04381 2H

Convection Patterns in a Pond,
W82-04461 2C

Wind Mixing and Restratification in a Lake Near the Temperature of Maximum Density,
W82-04573 2H

THERMAL WATER
The Geothermal Hydrology of Warner Valley, Oregon: A Reconnaissance Study,
W82-04496 1A

THUNDERSTORMS
Disaster by Flood,
W82-04618 2E

THUNERSTORMS
Thunderstorm in Agriculture and in Forest Management,
W82-04617 2B

TIDAL EFFECTS
Salinity Intrusion in Estuaries,
W82-04574 2L

The Unterweser Automatic Water Quality Measurement System,
W82-04588 5A

TIDAL MARSHES
Oregon Coastal Salt Marsh Upper Limits and Tidal Datums,
W82-04312 2L

TIDAL RANGE
Electromagnetic Measurements of Tidal Transports in Estuaries,
W82-04296 7B

TIDAL RIVERS
Electromagnetic Measurements of Tidal Transports in Estuaries,
W82-04296 7B

TIDAL WATERS
Modeling the Environmental Effects of a Navigation Channel in a Tidal Bay,
W82-04449 6G

TILE DRAINAGE
Simple Equations for Hooghoudt Equivalent Depth,
W82-04271 4A

Pumped Outlets for Drainage Systems,
W82-04364 8A

TITRATION
Chloride Determination in Automated Water Composition Monitoring (Chloridbestimmung in der Automatisierten Wasserbeschaffenheitskontrolle),
W82-04580 5A

TOILETS
Reducing the Flush,
W82-04654 3D

TONGUE RIVER BASIN
Water Rights, Allocation, and Conflicts in the Tongue River Basin, Southeastern Montana,
W82-04441 6E

TOOLIK LAKE
Effects of Petroleum Hydrocarbons on Plant Litter Microbiota in an Arctic Lake,
W82-04455 5C

TOPSOIL
Topsoil Management of Mined Soils,
W82-04571 4D

TOXICITY
Effects of Phenol on Oxygen Consumption in The Whelk, Bullia Digitalis (Dillwyn),
W82-04262 5C

Use of Stormwater Detention Basins for Neutralization and Special Treatment of Toxicants (Einsatz von Regenklarbecken zum Ausgleich und zur Sonderbehandlung Toxischer Abwasserstosse),
W82-04282 5D

Combined Effects of Cadmium and Zinc on a Lake Michigan Zooplankton Community,
W82-04379 5C

A Stress Function for Evaluating Strategies for Water Quality Management,
W82-04407 5C

Health Effects of Alternate Disinfectants and Their Reaction Products,
W82-04422 5C

Toxicity of Nitrite to Larvae of the Salamander Ambystoma Texanum,
W82-04529 5C

A Correlation Study of Biodegradability Determinations with Various Chemicals in Various Tests II. Additional Results and Conclusions,
W82-04534 5B

LIBRARY U. OF I. URBANA-CHAMPAIGN

TOXINS
Surrogate Parameter Analysis for Organic Priority Pollutants,
W82-04704 5A

TRACE ELEMENTS
Determination of Trace Elements in Seawater by Neutron Activation Analysis and Electrochemical Separation,
W82-04530 5A

TRACE METALS
Sedimentation Rates and Depositional Processes in Lake Superior from Pb210 Geochronology,
W82-04380 2J

Selected Trace Metals in the Upper St. Johns River and Their Land Use Relationships,
W82-04718 5B

TRACTIVE FORCES
Incipient Motion of Sand Particles on Side Slopes,
W82-04368 8D

TRANSMISSIVITY
Deep Well Disposal of Secondary Effluent in Dade County Florida,
W82-04442 5E

TRANSPIRATION
Spacing and Transpiration of Various Sized Clumps of a Desert Grass, Hilaria Rigida,
W82-04295 2D

TRICKLE IRRIGATION
Subsurface Trickle Irrigation Mangement with Multiple Cropping,
W82-04356 3F

TRIHALOMETHANES
The Identification and Treatment of Bromides and Trihalomethanes in Potable Water from the Pearl River at Jackson, MS: Evaluation of Toxicity on Species Diversity,
W82-04413 5A

Control of Trihalomethanes in Drinking Water,
W82-04425 5F

TURBIDITY
Coagulation Mechanisms: An Electron Microscopic Study Using Aluminum Sulfate,
W82-04423 5F

Ridge Regression Techniques Applied to Landsat Investigation of Water Quality in Lake Okeechobee,
W82-04440 2H

Continuous Monitoring of the Effluent Quality of an Activated Sludge Plant by Turbidity Measurement (Kontinuierliche Kontrolle Der Ablaufgute Einer Belebtschlammanlage Mittels Trubungsmessung),

SELECTED WATER RESOURCES ABSTRACTS

DEPOSITORY
UNIVERSITY OF ILLINOIS
AT URBANA-CHAMPAIGN

U.S. DEPARTMENT OF THE INTERIOR
MARCH 3, 1849

LIBRARY U. OF I., URBANA-CHAMPAIGN

VOLUME 15, NUMBER 11
NOVEMBER 1, 1982

W82-04751 -- W82-05900
CODEN: SWRABW

SELECTED WATER RESOURCES ABSTRACTS (SWRA) is produced by the Office of Water Research and Technology, U.S. Department of the Interior, and published monthly by the National Technical Information Service (NTIS), U.S. Department of Commerce.

SWRA is available to Federal agencies and their contractors or grantees in water resources research upon request, citing contract or grant number and sponsoring agency. Write: Office of Water Research and Technology, U.S. Department of the Interior, Washington, DC 20240. The **SWRA Journal** is also available on subscription from NTIS, 5285 Port Royal Road, Springfield, VA 22161. Annual subscription rates for the North American Continent are: Journal only, $100; Journal and Annual Indexes, $125; Indexes only, $50. Other addressees, write for prices.

Some documents abstracted in this journal can be purchased from NTIS. Price codes are given in the entries and a current code-price conversion table is printed on the outside back cover. Other documents are available from originating organizations or authors as indicated in the citation.

SELECTED WATER RESOURCES ABSTRACTS

A monthly publication of the Office of Water Research and Technology,
U.S. Department of the Interior

VOLUME 15, NUMBER 11
NOVEMBER 1, 1982

W82-04751 -- W82-05900

LIBRARY U. OF I., URBANA-CHAMPAIGN

The Secretary of the Interior has determined that the publication of the periodical is necessary in the transaction of the public business required by law of this Department.

As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This includes fostering the wisest use of our land and water resources, protecting our fish and wildlife, preserving the environmental and cultural values of our national parks and historical places, and providing for the enjoyment of life through outdoor recreation. The Department assesses our energy and mineral resources and works to assure that their development is in the best interests of all our people. The Department also has a major responsibility for American Indian reservation communities and for people who live in Island Territories under U.S. administration.

PREFACE

Selected Water Resources Abstracts, a monthly journal, includes abstracts of current and earlier pertinent monographs, journal articles, reports, and other publication formats. These documents cover water resources as treated in the life, physical, and social sciences and the related engineering and legal aspects of the characteristics, supply condition, conservation, control, use, or management of water resources. Each abstract includes a full bibliographic citation and a set of descriptors which are listed in the **Water Resources Thesaurus.** The abstract entries are classified into 10 fields and 60 groups similar to the water resources research categories established by the Committee on Water Resources Research of the then Federal Council for Science and Technology.

Selected Water Resources Abstracts is designed to serve the scientific and technical information needs of scientists, engineers, and managers as one of several services of the Office of Water Research and Technology. The cumlative SWRA file from 1968 and montlhy updates are available also in magnetic tape through lease from NTIS.

THE OFFICE OF WATER RESEARCH AND TECHNOLOGY DOES NOT PROVIDE COPIES OF DOCUMENTS ABSTRACTED IN THIS JOURNAL. Sufficient bibliographic information is given to enable readers to order the desired documents from local libraries or other sources.

Comments and suggestions concerning the contents and arrangement of this bulletin are welcome.

CONTENTS

SUBJECT FIELDS AND GROUPS

Please use the edge index on the back cover to locate Subject Fields and Indexes.

01 NATURE OF WATER

Includes the following Groups: Properties; Aqueous Solutions and Suspensions.

02 WATER CYCLE

Includes the following Groups: General; Precipitation; Snow, Ice, and Frost; Evaporation and Transpiration; Streamflow and Runoff; Groundwater; Water in Soils; Lakes; Water in Plants; Erosion and Sedimentation; Chemical Processes; Estuaries.

03 WATER SUPPLY AUGMENTATION AND CONSERVATION

Includes the following Groups: Saline Water Conversion; Water Yield Improvement; Use of Water of Impaired Quality; Conservation in Domestic and Municipal Use; Conservation in Industry; Conservation in Agriculture.

04 WATER QUANTITY MANAGEMENT AND CONTROL

Includes the following Groups: Control of Water on the Surface; Groundwater Management; Effects on Water of Man's Nonwater Activities; Watershed Protection.

05 WATER QUALITY MANAGEMENT AND PROTECTION

Includes the following Groups: Identification of Pollutants; Sources of Pollution; Effects of Pollution; Waste Treatment Processes; Ultimate Disposal of Wastes; Water Treatment and Quality Alteration; Water Quality Control.

06 WATER RESOURCES PLANNING

Includes the following Groups: Techniques of Planning; Evaluation Process; Cost Allocation, Cost Sharing, Pricing/Repayment; Water Demand; Water Law and Institutions; Nonstructural Alternatives; Ecologic Impact of Water Development.

07 RESOURCES DATA

Includes the following Groups: Network Design; Data Acquisition; Evaluation, Processing and Publication.

08 ENGINEERING WORKS

Includes the following Groups: Structures; Hydraulics; Hydraulic Machinery; Soil Mechanics; Rock Mechanics and Geology; Concrete; Materials; Rapid Excavation; Fisheries Engineering.

09 MANPOWER, GRANTS, AND FACILITIES

Includes the following Groups: Education—Extramural; Education—In-House; Research Facilities; Grants, Contracts, and Research Act Allotments.

10 SCIENTIFIC AND TECHNICAL INFORMATION

Includes the following Groups: Acquisition and Processing; Reference and Retrieval; Secondary Publication and Distribution; Specialized Information Center Services; Translations; Preparation of Reviews.

HETEROTROPHIC ASSIMULATION OF PHYTOPLANKTON AS AN INTEGRAL PART OF THE SELF PURIFICATION OF NATURAL WATERS,
Akademiya Nauk URSR, Kiev. Inst. Hidrobiologii.
M. I. Kuz'menko, and V. G. Klenus.
Hydrobiological Journal, Vol 16, No 5, p 103-104, 1980.

Descriptors: *Bacteria, *Algae, *Oxygen uptake, *Phytoplankton, Heterotrophic bacteria, *Self purification, Organic matter, Assimilative capacity.

Oxidative heterotrophic assimilation by phytoplankton and bacterioplankton was demonstrated by differences in oxygen uptake in natural water (18.75-21.80 mg 0 per g dry matter for algae and 65.09-101.42 for bacteria) and in water with added organic matter such as amino acids and sugars (19.75-65.20 mg 0 per g dry matter per hour of exposure for algae and 71.93-818 for bacteria). Oxidative heterotrophic assimilation of algae was 1.59-5.67 times greater than that of bacteria for the stated level of biomass when calculated per unit volume. (Cassar-FRC)

STUDIES ON OXYGEN TRANSFER MODELS,
Tokyo Univ. (Japan). Dept. of Urban Engineering.
T. Matsuo, and K. Hirayama.
Water Science and Technology, Vol 14, No 1/2, p 321-329, 1982. 7 Fig, 4 Tab, 12 Ref.

Descriptors: *Self-purification, *Turbulent flow, *Oxygen transfer, Model studies, Liquid film coefficient, Air-water interfaces, Energy dissipation, Temperature effects, Flow velocity, Eddies, Hydraulic properties.

The liquid film coefficient, a measure of the rate of oxygen transfer at air-water interfaces, depends on hydraulic parameters such as velocity, depth, and particularly turbulence characteristics of the flow. Two kinds of turbulence parameters were evaluated: the turbulence energy dissipation, corresponding to smaller-scale movements designated by Kolmogoroff's micro-scale, and the root mean square velocity fluctuation, corresponding to larger scale movements such as eddies. Results of laboratory experiments measuring the turbulence parameters and investigations on the effects of water temperature imply that for the mass transfer mechanism at the air-water surfaces, larger scale turbulent motion is dominant over smaller scale motion. CHARACTERIZATION OF PROPERTIES OF WATER,
Rochester Univ., NY. Distillation Research Lab.
K. Hickman, W. V. Kayser, D. K. Thakur, I. White, and H. J. Palmer.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-236555, Price codes: A04 in paper copy, A01 in microfiche.
Report, July, 1981. 27 p, 16 Fig, 1 Tab, 17 Ref. OWRT(No 3236)(1), 14-30-3236).

Descriptors: *Water properties, *Water vapor, *Surface tension, *Surfactants, *Water surface profiles, Physical properties, Vapor pressure, Air-water interfaces, Ice-water interfaces, Capillarity, Supercooling, Ice formation, Water, Reservoir storage, Water temperature, Water stress, Water cooling, Distilled water.

Research summaries are provided, covering studies on various aspects of the properties of water: vapor recoil; surface tension; the isothermal water-vapor interface. In studies of vapor recoil from non-aqueous liquids (triethanolamine) during steady-state evaporation under vacuum, addition of 20-microliter solutions of relatively involatile surfactants (erucic acid, Igepal CO-210 and CO-970, vitamin E acid succinate) produced rapid torpidity, with the degree of imparted surface stability due to both the surface-activity and interfacial concentration of the surfactant. In another study using a slower induction of evaporation from water supercooled below -12 degrees, instead of the surface dividing as the temperature fell, instantaneous formation of an icy layer pitted by conical depressions was observed; this was explained in terms of vapor recoil. Other studies included: superheating and surface tensions of water at temperatures lower than the ambient boiling point; calculations of surface tension and the evaporation coefficient at the isothermal interface; increases in surface temperatures accompanying known heat input to the surface; and mathematical and experimental reservoir storage study of mixing of hot water layers over denser colder water. (Zielinski-MAXIMA)

EFFECT OF WATER TURBULENCE ON ILLUMINATION AT DEPTH,
Akademiya Nauk URSR, Kiev. Inst. Hidrobiologii.
V. I. Bykovskiy.
Hydrobiological Journal, Vol 16, No 6, p 46-49, 1980. 1 Fig, 1 Tab, 11 Ref.

Descriptors: *Light penetration, *Turbulent flow, Algae, Productivity, Physical properties, Wave refraction, Flow, Wavelengths.

Light penetration into water of varying turbulence was studied in an aquarium equipped with a pump which produced turbulence without air entrapment. Illumination was measured at a depth of 0.27 m. The light attenuation factor correlated with turbulence and varied from 2.9-4.5 per meter for stagnant water to 4.8-6.4 per meter for highly turbulent flow (Reynolds number 200,000). Light of different spectral wavelengthes was unequally attenuated by the moving flow. The blue-violet range of the spectrum was attenuated 1.1-1.5 times more strongly than the red at flows of R = 20,000-30,000, but at R = 200,000 the difference disappeared. The yellow-green range of the spectrum correlated with turbulence and did not show any anomalies. Turbulent flow can be harmful to algal growth in two ways: by decreasing total illumination (decreases productivity) and by producing wave lenses or small areas of great light intensity (destroys cell pigments). THE EFFECT OF PRESSURE ON THE SOLUBILITY OF MINERALS IN WATER AND SEAWATER,
Rosenstiel School of Marine and Atmospheric Science, Miami, FL.
F. J. Millero.
Geochimica et Cosmochimica Acta, Vol 46, No 1, p 11-22, January, 1982. 9 Fig, 15 Tab, 48 Ref.

Descriptors: *Solubility, *Minerals, *Atmospheric pressure, *Seawater, Compressibility, *Surface water, Mathematical studies, Volumetric analysis.

Recently, several attempts have been made to use molal volume and compressibility data to estimate the effect of pressure on ionic equiliria such as the ionization of acids, the formation of ion pairs, and the solubiity of minerals in water and seawater. Equations are presented for estimating the effect of pressure on the solubility of minerals in water and seawater and for determining the volume and compressibility changes at one atmoshere of pressure. The values of the partial molal volume and compressibility in water and seawater are tabulated for several ions at temperatures ranging from 0 to 50 C. The large compressibility change found for the solubility of most minerals accounts for the large differences which have been observed between values of partial molal volume obtained from linear plots of compressibility versus atmospheric pressure and molal volume data. Calculated values for the solubility of several compounds in water were found to be in good agreement with direct measurements. Similar calculations for the solubility of minerals in seawater were also found to be in good agreement with direct measurements, providing that the surface of the solid phase is not appreciably altered. The reported tabulated data can be used to make reasonable estimates of the effect of pressure on the solubility of minerals and other ionic equilibria in water and seawater. (Carroll-FRC)

BACTERIOLOGICAL QUALITY OF SURFACE AND SUBSURFACE RUNOFF FROM MANURED SANDY CLAY LOAM SOIL,
Department of Agriculture, Ottawa (Ontario).
J. L. B. Culley, and P. A. Phillips.
Journal of Environmental Quality, Vol 11, No 1, p 155-158, January-March, 1982. 2 Fig, 5 Tab, 13 Ref.

Descriptors: *Agricultural runoff, *Bacteria, Fecal coliforms, Water quality, Coliforms, Water pollution sources, *Manure, *Farm wastes, Runoff, Seasonal variation.

The objectives of this study were to investigate the bacteriological quality of snowmelt surface and subsurface discharge from corn cropland receiving different rates of liquid dairy manure at different application times and to measure survival rates of indicator organisms in winter-spread manure. A gently sloping field of imperfactly drained Manotick sandy clay loam was divided into 14 plots which had been cropped in silage corn since 1973. After an intial year when no manure was applied, liquid dairy manure treatments at three rates and four different application periods were randomized and assigned to each plot for a period of 6 years. Liquid manure application rates averaged 105, 264, and 420 cubic meters per ha per year. The bacteriological quality of runoff from manured, corn-cropped sandy clay loam indicated that both spring snowmelt surface and subsurface discharge from winter applied treatments contained higher numbers of indicator organisms than did similar runoff from plots manured either the previous spring or fall. There was also some evidence that June storm surface runoff from spring treatments contained higher bacterial densities than did plots that received manure the previous winter or fall. Survival of fecal streptococcus organisms in surface applied frozen manure was noted, while both total coliform and fecal coliform densities declined to low

LIBRARY U. OF I., URBANA-CHAMPAIGN

levels within 40 days after application. Results indicate that land should be manured and plowed in the fall, prior to freeze-up, in order to minimize microbial densities in runoff during the following spring. (Baker-FRC)

CYCLIC FLUCTUATIONS IN THE FLOOD AREA AND RELATIONSHIP WITH THE DOUBLE (HALE) SUNSPOT CYCLE,
Indian Inst. of Tropical Meteorology, Poona.
H. N. Bhalme, and D. A. Mooley.
Journal of Applied Meteorology, Vol 20, No 9, p 1041-1048, 1981. 8 Fig, 2 Tab, 20 Ref.

Descriptors: *Flood forecasting, *Weather patterns, Forecasting, *Sunspots, Weather, Distribution patterns, Mathematical studies, *India, Western United States.

In this paper the possible relationship between the double sunspot cycle and the variation of the Flood Area Index over India is investigated. Harmonic analysis is used, and power spectrum and cross-spectrum analysis to relate the Flood Area Index series to the series of sunspot numbers of the double sunspot cycle. The power spectrum analysis reveals a highly significant approximately 22 year cycle in the Flood Area Indices over India. Harmonic analysis of the same record also shows a well marked 22-year Flood Area Index cycle in phase with the souble sunspot cycle. The Drought Area Index series shows a weak quasi-periodicity of 2.7-3.0 years. Cross spectrum analysis presents strong evidence that the 22 year FAI cycle over India is related to the double sunspot cycle. Further, the 22 year FAI cycle is nearly in phase with the double sunspot cycle. Harmonic dial analysis s hows that all of the large scale flood events over India occurred consistently in the major sunspot cycle and none occurred in the minor sunspot cycle. Large scale drought events have no preference to the phase of the sunspot cycle. The strong evidence for a relationship between the areal extent of the floods over India and the double sunspot cycle reported shares in the kind of sun climate relationship reported for the western United States, but for flood rather than drought. NUMERICAL MODELING STUDY OF LAKE PONTCHARTRAIN,
NOAA Data Buoy Office, NSTL Station, MS.
G. D. Hamilton, C. W. Soileau, and A. D. Stroud.
Journal of the Waterway Port Coastal and Ocean Division, Proceedings of the American Society of Civil Engineers, Vol 108, No WW1, p 49-64, February, 1982. 13 Fig, 1 Tab, 17 Ref.

Descriptors: *Hydrologic models, *Lakes, *Wind tides, *Water level fluctuations, Mixing, Particulate matter, Numerical analysis, *Water circulation, Model studies, Tidal effects, Monte Carlo method, Mathematical models, Mathematical studies, Wind-driven currents, Friction, Advection, Surface velocity, *Lake Pontchartrain, Louisiana.

Actual wind circulation, water levels, and particulate matter dispersion in Lake Pontchartrain were simulated by a Hansen-type hydrodynamic numerical model utilizing an explicit numerical difference scheme. The model utilizes a leap-frog integration through time of the two-dimensional Eulerian form of the hydrodynamic equations to achieve a dynamical boundary-value solution of tidal order. Differential equations are derived by integrating x and y velocity components through a layer of assumed uniform density to yield vertically averaged mean components. The model also includes terms to account for the rotation of the earth, dissipative friction, and wind and tidal forcing. A Monte Carlo stochastic process helps to define diffusion and advection. The present paradigm was successfully applied to the estimation of lake surface movement by tides and wind and to the modeling of injunction and plume dispersion of particulate matter in lakes. APPLICATION OF A TWO-DIMENSIONAL MODEL OF FORMATION OF STORM RUNOFF TO CALCULATION OF THE RAIN-WATER COLLECTOR-DRAIN DISCHARGE FROM AN URBANIZED TERRITORY,
Akademiya Nauk SSSR, Moscow. Inst. Vodnykh Problem.
V. N. Demidov, and N. P. Lobanskaya.
Water Resources, Vol 8, No 2, p 126-132, March-April, 1981. 2 Fig, 3 Ref. Translated from Vodnye Resursy, No 2, p 65-71, March-April, 1981.

Descriptors: *Urban areas, *Drainage engineering, *Storm runoff, Runoff, Urban runoff, *Model studies, *Industrial development, Rainfall-runoff relationships, *Nizhnekamsk, USSR.

A two-dimensional model of runoff formation was used to calculate the collector drain discharge at a 0.365 sq km industrial complex under construction at Nizhnekamsk. It was possible to account for the characteristics of the relief of an urbanized area, the characteristics of its underlying surface, and the parameters of the rainwater collecting system. Comparing the results of the two-dimensional model with those of the isochrone method showed that the isochrone method overestimated values of maximum water discharges by as much as 38%. The two-dimensional method can also be used for designing a collection system. (Cassar-FRC)

ATMOSPHERIC MOISTURE TRANSPORT AND THE WATER BALANCE OF THE MEDITERRANEAN SEA,
Lisbon Univ. (Portugal).
J. P. Peixoto, M. de Almeida, R. D. Rosen, and D. A. Salstein.
Water Resources Research, Vol 18, No 1, p 83-90, February, 1982. 7 Fig, 1 Tab, 15 Ref.

Descriptors: *Atmospheric water, *Evaporation, *Hydrologic budget, Wind, Precipitable water, *Mediterranean Sea, Water vapor, Climatology, Weather patterns, Hydrologic cycle, Salinity, Air circulation, Precipitation rate, *Water balance.

The water balance of the Mediterranean Sea was obtained from the net difference between evaporation and precipitation rates by evaluating the divergence of the atmospheric flux of water vapor over the region. Upper air data from 1968-1973 were used to compute this value. The net difference between evaporation and precipitation from this study was 55,000 cu m per sec, compared with 59,000-67 cu m per sec obtained by other authors using more classical methods. Maps are printed showing the two-dimensional fields of precipitable water, the vertically integrated water vapor flux vector, and the divergence of water vapor over the region. The Mediterranean is not a closed system. Moisture enters from distant sources including the Atlantic, and a larger amount of water vapor is exported from the area to the Middle East and northeast Africa. Precipitable water averages 22.4 kg per sq m and totals 56 billion cu m over the whole sea. Three main centers of high water vapor content (over 24 kg per sq m) are found over the western Mediterranean, the Aegean, and the Levantine basin. Minima are found over desert areas, regions of high terrain, and over islands. Although the moisture transport pattern over the Mediterranean is generally west-to-east, there are nonuniformities. The Alps block the dominant westerlies and lead to dry air in the northern Adriatic. Drier air over Turkey is related to topographic effects. Southward transport dominates in central and eastern Mediterranean and northern transport over the Alboran Sea and Italy. The net meridional flow is 20 kg per m southward. Areas of strong divergence are found in the Levantine Basin and from south of Italy to the Libyan coast. Convergence zones, less widespread, are found over the Aegean, the Adriatic, the south of France, and the west African coast towards Morocco. (Cassar-FRC)

PEAK RUNOFF MODEL COMPARISON ON CENTRAL ILLINOIS WATERSHEDS,
Illinois Univ. at Urbana-Champaign. Dept. of Agricultural Engineering.
S. Mostaghimi, and J. K. Mitchell.
Water Resources Bulletin, Vol 18, No 1, p 9-13, February, 1982. 4 Tab, 12 Ref.

Descriptors: *Watersheds, *Runoff rates, *Flood peaks, Mathematical models, Model studies, Performance evaluation, Statistical analysis, Areal hydrology, Illinois.

Although estimates of peak flows are needed for the design of the thousands of hydraulic conveyances and structures built each year, it is physically and economically impossible to measure runoff from each watershed for which such and estimate is required. As a result, it is necessary to extend the results of peak runoff measurements made in a small number of watersheds to ungaged areas. Four models for predicting peak runoff rates in watersheds of mild topography were selected and compared to determine the model most applicable to the small agricultural watersheds of east-central Illinois. The 15 watersheds used for this study are representative of slopes, soils, and land-use patterns found throughout much of the area. Rainfall and runoff measurements were available continuously since 1949 for four watersheds at Allerton Park, while data were available for the other watersheds for various lengths of time between 1955 and 1970. The Cypress Creek, Rational, Chow, and Soil Conservation Service (SCS) peak runoff models were found to be appropriate for the available data and physical conditions of these watersheds. Evaluations of the performances of these models showed that: (1) the Cypress Creek model underpredicted peak flow for most of the watersheds; (2) the Rational model overestimated the peak flow rates for most of the watersheds; (3) the Chow model generally resulted in better estimates of peak runoff for the Allerton watersheds than for the other watersheds; and (4) the SCS model was considered to be best for predicting peak runoff rates from these mild topography, agricultural watersheds. Error-mean-square tests confirmed that the SCS model predicted peak runoff rates better than the other three models for all but two watersheds. (Carroll-FRC)

ON THE RELATIONSHIP BETWEEN THE RELIABILITY OF PARAMETER ESTIMATES AND HYDROLOGIC TIME SERIES DATA USED IN CALIBRATION,
Monash Univ., Clayton (Australia). Dept. of Civil Engineering.
G. Kuczera.
Water Resources Research, Vol 1, No 1, p 146-154, February, 1982. 4 Fig, 3 Tab, 17 Ref.

Descriptors: *Hydrologic models, *Streamflow, *Time series analysis, Parametric hydrology, Model studies, Precipitation, Stochastic process, Ocala, Florida, Watersheds, Rainfall-runoff relationships, Groundwater, Runoff, Estimating, Calibrations, Soil water.

Parameters of conceptual hydrologic models are calibrated using limited information, input-output time series data, such as precipitation and streamflow. The sources of stochasticity in these models are identified. Conditions under which parameter estimates are consistent are: (1) the structure of the model represents without bias the internal hydrologic transfers, (2) the hydrologic transfers are deterministic in the sense that state-dependent fluxes can be predicted with negligible error, and (3) measurement errors on observable driving fluxes are negligible. Improving the stability of parameter estimates is considered. On the first information level the first two moments of measurement errors are used to make large sample bias corrections. The second level uses time series data corresponding to storage volumes such as groundwater and

soil moisture to remove the source of inconsistency due to erroneous influence of estimated storage volume and to improve the stability of parameter estimates. Proper exploitation requires that the estimation procedure exploits the interdependence of model equations arising from coupled model structure and correlated disturbances. The generalized least squares procedure offers a promising approach for exploiting all available time series information in model calibration. An example features hydrological data from a watershed near Ocala, Florida. (Cassar-FRC)

RIVER-BASIN SIMULATION IN SYSTEMS WITH LARGE RESPONSE TIME,
Massachusetts Inst. of Tech., Cambridge, Dept. of Civil Engineering.
V. P. Nogueira, J. L. Wilson, and K. Strzepek.
Journal of Hydrology, Vol 51, No 1-4, p 159-168, May, 1981. 6 Ref.

Descriptors: *Simulation analysis, *River basins, Performance evaluation, Optimization, Cost analysis, Systems analysis, Mathematical equations, Mathematical studies, Markov process.

Two common problems encountered in the static simulation of a river basin are the determination of the simulation length and the balancing of the effect of the initial conditions on the system measures of performance. Since it is impossible to formulate general solutions to these problems, some general guidelines are developed and applied to the specific case of a simple system in which a synthetic sequence was used as input and an output sequence was obtained and assumed Markovian. The results show that Conway's rules, which suggest that data from some initial period be excluded from consideration and that starting conditions be chosen which make the necessary excluded interval as short as possible, can be implemented even though they seem to be rather general and loose. Care must be taken for each particular case, and a general idea about the output to be obtained must be developed before any rational action can be taken or any simplifying assumptions made. The costs of estimation must be balanced against the costs provoked by errors of estimation in order to determine the run length. Such analysis should be made even when computer costs are fixed or constant, so that compensation may be made for errors of estimation. Whenever possible, costs should be weighted before deciding between a long run and a series of replicated runs. Generally, replication results in increased bias due to the effect of initial conditions but decreased variance. It is suggested that this methodology can be used for practically every case if appropriate modifications are made. (Carroll-FRC)

ESTIMATION OF FLOOD PEAKS WITH LIMITED HYDROLOGIC DATA,
Ottawa Univ. (Ontario). Dept. of Civil Engineering.
E. J. Schiller, and J. O. Ngana.
Journal of Hydrology, Vol 51, No 1-4, p 151-157, May, 1981. 3 Fig, 3 Tab, 3 Ref.

Descriptors: *Flood peak, *Hydrologic data, *Prediction, Flood flow, Mathematical models, Mathematical equations, Developing countries, Tanzania, Africa.

In developing countries, designers of water projects are often confronted with the need to develop projects making the best use of very scanty hydrologic data and limited available capital. Flood data for instance, are often required on rivers having little or no recorded hydrologic data. In Tanzania, the government plans to proceed with hydropower and rural development in the Rukwa region, for which hydrologic data is very scarce. However, the drainage basins of the nearby Mbeya region are quite well monitored. Statistical analyses of the discharge data from selected catchments in the Mbeya region were compared with the TRRL (United Kingdom Transport and Road Research Laboratory) flood model results for the region. The high level of agreement between the results indicated that the TRRL model is applicable to Mbeya catchments. A regional flood-frequency study for the Mbeya catchments resulted in the development of a regional frequency curve of discharge ratios and of a curve of mean annual flood versus drainage areas of the basins. The TRRL flood model results and the regional frequency curve for the Mbeya region were then utilized in the Rukwa catchments. The results obtained from these two methods agreed well with each other, suggesting that both the TRRL flood model technique and the derived regional frequency curve can be used fairly well on ungauged catchments in the Mbeya and Rukwa regions where hydrologic similarity exists. Although more data would increase the accuracy of the results of the two methods, each method produced results of useful accuracy based on the limited data available. (Carroll/FRC)

Available from the OFSS, USGS Box 25425, Fed. Ctr. Denver, CO 80225, Price: $7.50 in paper copy, $3.50 in microfiche. Geological Survey Open-File Report 81-417, 1981. 55 p, 1 Fig, 4 Ref, Append.

Descriptors: *Computer programs, *Geomorphology, *Small watersheds, *Drainage systems, Hypsometric analysis, Drainage density, *South Carolina, Sumter National Forest.

This report describes a computer program, written in Basic, that facilitates quantitative analysis of drainage basins and channel networks. The program was used to inventory 2,000 small watersheds in Sumter National Forest, South Carolina during 1980 and 1981. Drainage basins and stream segments were delineated in color on mylar overlays over U.S. Geological Survey 1:24,000-scale maps. Drainage basin characteristics were quantified and stored on eight-inch diskettes. The program can produce printouts and plots that summarize geomorphic data for each watershed. The program is adaptable to other locations. (USGS)

COASTAL FRESH WATER DISCHARGE IN THE NORTHEAST PACIFIC,
Alaska Univ., Fairbanks. Inst. of Marine Science.
T. C. Royer.
Journal of Geophysical Research, Vol 87, No C3, p 2017-2021, March 20, 1982. 7 Fig, 17 Ref.

Descriptors: *Precipitation, *Water currents, Fresh water, Storms, Streams, Stream flow, Orography, Mountains, Pacific Ocean, Alaska, Coastal waters, Coastal streams, Advection.

In this paper the sources of runoff and advection for the northeast Pacific are discussed. Seasonal changes of the runoff and their effects on the coastal circulation are considered. The high precipitation rates produce large fresh water discharges which enter the ocean by way of numerous small rivers and streams. Therefore they act as a line source rather than a point source. This coastal discharge contributes at least 40% of the fresh water that enters the northeast Pacific from the atmosphere. The discharge is comparable to the mean annual discharge of the Mississippi River system. The fresh water creates a cross-shelf density gradient that drives an alongshore baroclinic jet. The width of this jet is less than 25 km, with speeds in excess of 100 cm/second. It extends along the coast from southeast Alaska at least to Kodiak Island. The flow is apparently maintained as a narrow current adjacent to the coast by wind stress that causes downwelling conditions here throughout most of the year. The coastal mountain ranges bordering the Gulf of Alaska act as a barrier to the storms that move easterly across the North Pacific. Adiabatic elevation of these moist air masses causes very high rates of precipitation. (Baker-FRC)

THE RESIDENCE TIME OF THE FRESHWATER COMPONENT IN THE ARTIC OCEAN,
Rosenstiel School of Marine and Atmospheric Science, Miami, FL.
H. G. Ostlund.
Journal of Geophysical Research, Vol 87, No C3, p 2035-2043, March 20, 1982. 10 Fig, 3 Tab, 22 Ref.

Descriptors: *Ocean circulation, *Natural waters, Upwelling, Water currents, Dating, Snowmelt, Ocean ice, Arctic, Rivers, Runoff, Arctic Ocean, Polar regions, Arctic zone.

The time function of bomb tritium concentrations in river runoff to the Arctic Ocean was reconstructed from published data on tritium in precipitation, 1959-1975. The relationship between tritium and salinity indicated that sea ice melt and freezing affect the upper 10-60 meters of water in the Nansen Basin, increasing toward the Canada Basin to about 150 meters. The average age of the freshwater component is about 11 years from its first appearance at the shelf to its emergence from thee basin as a constituent of the modified Atlantic water in the East Greenland Current. In the Canada Basin the modified Atlantic water itself has the same residence time, since mixing may occur in several steps. The freshwater residence times could be revised downward by 1 or possibly 2 years if there is an unexpectedly large effect of air-to-sea molecular transport during initial formation of the halocline water. There are clear isotopic indications of snowmelt water penetrating the ice and freezing on its underside. In 1979 waters west of the Lomonosov Ridge down to 1200 meters and east of the ridge even at 2500 meters contained tritium at concentrations higher than one would expect in 1957 Norwegian Sea water, and most likely these waters entered the basin after 1965. This means that at these places and depths the Atlantic source waters are probably younger than 16 years and definitely younger than 20 years. (Baker-FRC)

Descriptors: *Rainfall, *Flood hydrographs, Hydrographs, Lakes, Flood control, Precipitation, South Africa, Graphical analysis, Mathematical studies, Graphical methods, Simulation.

In order to develop an efficient and careful system of management of the movement of water within

LIBRARY U. OF I., URBANA-CHAMPAIGN

the scenic Wilderness Lakes in the south eastern Cape area of South Africa, a collaborative program was launched which has as one of its aims the development of a mathematical model of the dynamics of the Lake system. A major application of the lake system model is the simulation of lake level responses to the inter-lake exchanges during various combinations of flood events in the major influent streams and sand bar obstructions across the Touw River mouth. Different ameliorative measures can then be superimposed on the system model and their effects on the system simulated and evaluated. The extreme value analysis of 39 years of daily rainfall records revealed clear relationships between extreme rainfalls, return periods, durations equal to or greater than one day, and area. Graphs are presented which allow the user to determine an areal correction factor for a specific duration, return period and area. When multiplied by the relevant extreme rainfall for the whole area, the correction factor produces an extreme rainfall for the sub-area in question. Comparisons with other methods available in South Africa for estimating areally averaged design rainfalls suggest that lower return period rainfalls were usually below the ones determined in this study. The results warrant their use as input in the generation of improved flood hydrographs for the Wilderness Lakes study. (Baker-FRC)

RAINFALL INTERSTATION CORRELATION FUNCTIONS: III. APPROXIMATIONS TO THE ANALYTICALLY DERIVED EQUATION OF THE CORRELATION FUNCTION FOR AN EXPONENTIAL STORM MODEL COMPARED TO THOSE FOR A RECTANGULAR AND A TRIANGULAR STORM,
Institute for Land and Water Management Research, Wageningen (Netherlands).
P. T. Stol.
Journal of Hydrology, Vol 52, No 3/4, p 269-289, July, 1981. 2 Fig, 5 Tab, 13 Ref.

Descriptors: *Rainstorms, *Correlation analysis, *Mathematical models, Numerical analysis, Mathematical equations, Rainfall, Precipitation.

The rainfall interstation correlation function can be analytically derived on the basis of a storm model. The interstation correlation function for the exponential storm model has a complicated structure and contains an arbitrary storm parameter (b) which must be established before the interstation correlation function for the model can be numerically evaluated. Choices for this parameter include (b) based on the shape of the storm profile, (b) based on minimum rainfall amounts that still can be observed, or (b) based on the storm volume of a triangular storm which has the same storm width. When the last choice is selected, it is possible to simplify the complicated structure of the correlation function for the exponential storm mode by means of sequential best approximations. The structure and properties of the correlation function for the rectangular, the triangular, and the exponential storm models can be compared using this simplified approximating form, providing insight into the behavior of the three storm models and their impacts on interstation correlation functions. In sampling rainfall data for correlation analysis, the effects of storm maximum, storm width, fraction of dry days, and area size should receive particular consideration. (Carroll-FRC)

A SELF-EVALUATING DISDROMETER FOR THE MEASUREMENT OF RAINDROP SIZE AND CHARGE AT THE GROUND,
Auckland Univ., (New Zealand). Dept. of Physics.
C. D. Stow, and K. Jones.
Journal of Applied Meteorology, Vol 20, No 10, p 1160-1176, 1981. 18 Fig, 2 Tab, 20 Ref.

Descriptors: *Rain, *Measuring instruments, Disdrometer, Rainfall, *Raindrop size.

This article considers the concept of instrument design to minimize effects of overlap and splashing in the measurement of raindrop size and describes an experiment which was conducted to provide direct evidence of inadmissible or unreliable data on drop size and charge, which should enable more useful spectra to be obtained than previously was possible. Fundamental errors include drop overlap which occurs at times of simultaneous occupation of the sampling volume by more than one drop, splashing, and the influence of the wind. The disdrometer described can determine the sizes of individual drops in the range of 0.1-2.5 mm radius and charges within the limits of magnitude 0.1-10 pC. Drop velocity and the detection of drop overlap within the charge sensitive volume can be accomplished by the use of two size detectors. Non-ideal data arising from natural conditions, measuring sites, and from fundamental or unavoidable deficiencies in disdrometer design could be tested and monitored automatically using a central processor under software control. The performance of the instrument was tested using individual drops generated in the laboratory and through exposure to natural rain falling through an aperture into a chamber shielded from wind and associated turbulence. Some improvements in the design of the current disdrometer are suggested. (Baker-FRC)

MOISTURE ANALYSIS FROM RADIOSONDE AND MICROWAVE SPECTROMETER DATA,
Florida State Univ., Tallahassee. Dept. of Meteorology.
K. J. Haydu, and T. N. Krishnamurti.
Journal of Applied Meteorology, Vol 20, No 10, p 1177-1191, 1981. 11 Fig, 27 Ref.

Descriptors: *Moisture profiles, *Spectrometers, Microwaves, *Remote sensing, Potential rainfall, Measuring instruments, Satellite technology, Moisture availability, Precipitation, Rainfall, *Atmospheric water.

This study exploited the objective of providing a detailed analysis technique for moisture over several vertical levels in the atmosphere. Two major problems were encountered: the need to formulate some type of a correction scheme to calibrate the satellite-derived total precipitable water and the development of an objective technique to obtain the vertical distribution of moisture. The method of analysis uses satellite, upper air and surface data. A brief overview of the microwave sensors on board Nimbus 5 and 6 is also included. The technique provided uses the radiosonde data sets to calibrate the satellite field of total precipitable water. The calibrated satellite-derived field is then used along with ship and coastal reports of moisture and thus provides a mapping of specific humidity at several levels in the troposphere. Using these procedures, analyses for several case studies were performed. The resultant maps showed detailed distributions of specific humidity along with interesting climatological features. A reasonable acceptance of the available aerological data sets by the analysis scheme is also demonstrated. (Baker-FRC)

DETERMINATION OF THE TOTAL PRECIPITABLE WATER BY VARYING THE INTERCEPT IN REITAN'S RELATIONSHIP,
Consiglio Nazionale delle Ricerche, Bologna (Italy).
C. Tomasi.
Journal of Applied Meteorology, Vol 20, No 9, p 1058-1069, September, 1981. 10 Fig, 17 Ref.

Descriptors: *Probable maximum precipitation, *Weather forecasting, Mathematical studies, Rainfall, Forecasting, Rain, *Precipitation, Dewpoint, Temperature.

Reitan in 1963 proposed a relationship between the total precipitable water and the dewpoint temperature at ground level in which the intercept was found to be a function of the scale height of the atmospheric water vapor and of the ground temperature. The scale height was closely related to the features of the vertical moisture profile in the low troposphere. The ground temperature is responsible for diurnal and seasonal variations of the intercept which are of little importance. The slope coefficient has a constant value. Using this as a base, a method is proposed which determines the nocturnal time pattern of the intercept by linear interpolation in time between the daytime estimates obtained from spectral hygrometer measurements. The nocturnal time pattern of the total precipitable water can be calculated from Reitan's relationship using these interpolated values of the intercept together with the nocturnal measurements of the dew point temperature at ground level. This method was satisfactorily applied to spectral hygrometer measurements made on several days. Estimates of the total precipitable water at two stations of the Po Valley were obtained from Reitan's relationship by using local measurements of the dew point temperature at ground level and suitable values of the intercept. FORESEEABLE EFFECTS OF CO2-INDUCED CLIMATIC CHANGE: FRESHWATER CONCERNS,
Oak Ridge National Lab., TN. Environmental Sciences Div.
C. C. Coutant.
Environmental Conservation, Vol 8, No 4, p 285-297, Winter, 1981. 3 Fig, 33 Ref.

Descriptors: *Carbon dioxide, *Climatology, *Research priorities, Air pollution, Temperature effects, Precipitation, Ecological effects, Water supply, Productivity, Species distribution, Sinks, Reservoirs, Water resources development, Arid climates, Streamflow, Water allocation, Aquatic life, Irrigation, Water pollution, Weather patterns, Cold regions, Algae, Eutrophication, Organic carbon, Estuaries.

The possible effects of increases in atmospheric carbon dioxide are a 2-3 C increase in global mean annual surface temperatures (least near the equator and most at 80 degrees north latitute, with anomalies in many locations) and precipitation changes (increased rainfall in some zones and increased aridity in others). These potential climatic changes many profoundly affect water resources availability and net productivity relationships and species distribution in aquatic ecosystems. High ranking research priorities include determination of the quality and quantity of organic materials transported by rivers into the ocean under present CO2 atmospheric conditions, determining whether estuarine or marine environments are a significant sink for river carbon, determination of the effects of CO2 enrichment of the air and concurrent temperature and precipitation changes on aquatic productivity and eutrophication of lakes, determination of changes in geographic ranges of commercially important and exotic aquatic species due to increased temperature, and development of plans for constructing water storage reservoirs in areas of increasing aridity. Medium-rank research priorities concern organic carbon deposits in sediments as a carbon sink, changes in water pollutant loads, effects on northern aquatic ecosystems from the elimination of permafrost, and the role of carbon in the organic load of rivers entering the sea. Several low-ranking priorities are also listed. (Cassar-FRC)

Journal of Hydrology, Vol 55, No 1/4, p 303-319, 1982. 5 Fig, 1 Tab, 14 Ref.

Descriptors: *Atmospheric precipitation, *Rainstorms, *Statistical analysis, Arid climates, Saudi Arabia, Storms, Seasonal variation, Coefficient of variation, Forecasting.

Separation of point precipitation records into statistically independent storms is done according to the criterion of exponentiality of the time between storms. If the coefficient of variation for time between storms is unity, the storms are considered independent. An algorithm is given for obtaining the above coefficient from a given storm sequence for successively larger minimum storm separation. Estimates of the time between independent storms obtained in this manner produce Poisson distributions of annual precipitation which agree well with observed distributions at 3 arid climate sites in Saudi Arabia. Values of time between independent storms from 17 stations with annual rainfalls varying from 24 to 5107 mm correlate with the rainy season monthly precipitation, providing a means of estimating time between independent storms from mean annual rainfall and mean length of rainy season. REVISED RAINFALL FREQUENCY ANALYSIS FOR HOUSTON,
Rice Univ., Houston, TX. Dept. of Environmental Science and Engineering.
T. C. Bouvette, J. L. Lambert, and P. B. Bedient.
Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 108, No HY4, p 515-528, April, 1982, 7 Fig, 6 Tab, 24 Ref.

Descriptors: *Rainfall, *Frequency analysis, Mathematical studies, Regional analysis, Precipitation, Frequency distribution, Houston, Urban areas.

A study was designed to determine whether significant rainfall pattern and intensity changes have occurred in the Houston area since 1960. Such changes are associated with contemporary urban development and could help to explain the severe flooding problems encountered in recent years. Data was analyzed by four Houston area stations. The data indicated that the downtown station is receiving less rainfall and the areas around Houston are receiving more rainfall, as the Double Mass analysis illustrated. The 100 yr design storms indicated an increase in rainfall intensity occurring around the Houston area, while the downtown 100 yr design stroms indicate a decrease in rainfall intensity since the 1960 United States Weather Bureau effort. The number of recorded extreme events occurring downtwon has also diminished since 1960. The change in rainfall intensity could have come about through a shading effect caused by the increased density of tall buildings downtown, which could cause inaccurate gaging. However, this does not explain the observed increase in rainfall outside the downtown area. The increased extreme event intensities outside of the downtown area indicate a potential problem in designing drainage and sewer systems. Reevaluation of design storm parameters should be done periodically, no less than once every five years in growing urban centers. (Baker-FRC)

METAL SURVEYS IN SOUTH AFRICAN ESTUARIES. I. SWARTKOPS RIVER,
National Physical Research Lab., Pretoria (South Africa).
R. J. Watling, and H. R. Watling.
Water S. A., Vol 8, No 1, p 26-35, January, 1982. 4 Fig, 10 Tab, 9 Ref.

Descriptors: *Trace metals, *Estuaries, Estuarine environment, Water pollution sources, Rivers, South Africa, Copper, Lead, Zinc, Nickel, Oysters, Monitoring, Brickworks, Outfalls, Municipal sewage.

The results of a detailed trace metal survey of the Swartkops River, South Africa, are reported. Oysters growing at the mouth of the river contained considerably more zinc, copper and lead than had been determined for the same species growing at other locations on the South African coast. Surface water samples were collected in 2.5 foot high density polyethylene bottles. Surface sediment and sediment core samples were also collected up to 15 km from the mouth of the Swartkops River and analyzed for up to 16 elements. Four main areas of contamination were thus found: at Redhouse, Swartkops, a brickworks, and Amsterdam Hoek. Large accumulations of zinc, copper lead and nickel by the oysters at the mouth confirm the presence of greater than normal metal concentrations in the river. The Swartkops area may obtain a contribution from the power station effluent, and Uitenage and Despatch municipal effluents probably contribute to the contamination of the Redhouse area. The Fishwater Flats sewer outfall appears to be a further source of contaminants but may not be significant in terms of metal buildup, as tidal sweep disperses the effluent relatively quickly. At the present time the concentration of metals in the area is not viewed as cause for alarm. Monitoring should be made at specific sites of input of these contaminants to establish long term trends. VARIATIONS IN MOISTURE DEFICITS OVER THE MAIZE-GROWING REGION OF SOUTH AFRICA II: TEMPORAL ASPECTS,
Missouri Univ., Columbia. Dept. of Atmospheric Science.
J. F. Gillooly, and T. G. J. Dyer.
Water S. A., Vol 8, No 1, p 9-15, January, 1982. 8 Fig, 2 Tab, 15 Ref.

Descriptors: *Rainfall, *Temporal distribution, Precipitation, South Africa, Distribution, Semiarid climates, Seasonal variations, Moisture availability, Moisture, Plants, Maize.

A description of temporal variations in moisture deficits over the period of 1945 to 1974 in the maize-growing region of South Africa is offered. Temporal changes in moisture deficits were considered on two scales: first on a seasonal basis and then on a monthly time scale. Within each time scale temporal variation was examined on a regional basis and then for the maize growing area as a whole. These time series were then analyzed using Jenkinson's modified version of harmonic analysis, which removes the constraint placed on resolution in straightforward harmonic analysis and avoids the need to guess a maximum lag for use in the conventional spectral approach to analyses over the frequency domain. Moisture deficits were shown to be more severe and more variable in the dry western parts of the maize growing region of South Africa. The greater variability of moisture deficits in the west is of relevance to agricultural planning, as this is the area where maize is commonly grown under marginal dryland conditions. It has been possible to isolate months, or groups of months, during the growing season when deficits exhibit marked variability. Finally, the isolation of periods of above- and below-normal moisture deficits between 1945 and 1975 suggests that the moisture deficit term provides a potentially useful index for assesssing the impact of climatic variability on food production in South Africa. GLACIERS AND THEIR FLUCTUATIONS,
Swiss Federal Inst. of Tech., Zurich.
F. Muller.
Nature and Resources, Vol 16, No 2, p 5-11, April/June, 1980. 5 Fig, 1 Tab.

Descriptors: *Glaciers, *Climatic, *Climatology, Glacial drift, Glacier mass balance, Monitoring, International commissions.

Two international bodies, the Permanent Service on Fluctuations of Glaciers (PSFG) and the Temporary Technical Secretariat (TTS) for the World Glacier Inventory, both located at the Swiss Federal Institute of Technology, have been created to advance snow and ice research in the contexts of hydrology, technology, and climatic change. This TTS is charged with coordinating and assisting national glacier inventory efforts, collecting and standardizing data, making the data computer compatible in one system, eventually producing a global summary, and initiating and supporting analysis based on these data. The objective of the PSFG is to produce a global set of data on the fluctuations of glaciers which will provide a general view of the changes, encourage more extensive measurements, facilitate consultation, and serve as a data base for monitoring climatic change. Twenty-seven countries participate and regularly submit data on glaciers within their national boundaries or collected by their scientists elsewhere. Although it is generally accepted that glacier-tongue fluctuations are caused by changes in climatic conditions, data collected on over 800 glaciers show that there are great differences in the reactions of individual glaciers. However, the statistically averaged behavior of a sufficiently large number of glaciers within a certain region reflects changes in climate very reliably. It appears that mean annual temperature variations of less than 1 C can have a profound effect on glaciers, and that in some areas the summer temperatures have more influence than annual mean values. However, the complex chain of causal dependence within the climate-glacier relationship is not fully understood. Long-term measurements of both mass balance and climatic parameters on local and regional levels are needed in order to construct reliable quantiative models for prediction. (Carroll-FRC)

ICEBERGS: TECHNOLOGY FOR THE FUTURE,
Cambridge Univ. (England).
H. E. Huppert.
Nature (London), Vol 285, No 5760, p 67-68, May 8, 1980.

Descriptors: *Icebergs, *Water transport, *Water supply, Ice-water interfaces.

Presentations to a conference on The Use of Icebergs organized by the International Glaciological Society are summarized These presentations focussed on the physical characteristics of icebergs, including the way they break up and roll over; their melt-rate; and the feasibility of capturing and towing icebergs to locales where they could be used as freshwater supplies. Studies of the break-up of icebergs indicate that only very large ice sheets will remain intact as they drift far from their sources. Scaled towing tests conducted by Iceberg Transport International indicate that the most efficient means of propuslion is by hauling the iceberg on lines attached to a very large parachute drogue ahead of the iceberg. Reasonable efficiency may be achieved by using two drogues. Although it may be possible to process icebergs for water supply supplements using existing technology, little is known about the environmental effects of moving icebergs in shipping lanes could result in accidents. A MECHANISM FOR THE FORMATION OF LARGE ICEBERGS,
National Hydrology Research Inst., Ottawa (Ontario).
G. Holdsworth, and J. E. Glynn.
Journal of Geophysical Research, Vol 86, No C4, p 3210-3222, April 20, 1981. 8 Fig, 1 Tab, 32 Ref.

Descriptors: *Icebergs, *Ice breakuup, *Floating ice, *Vibrations, Glaciers, Ocean waves, Tensile stress, Stress, *Antarctica.

The Antarctic ice sheet is connected to significant peripheral areas of floating ice, which calve to form icebergs, resulting in substantial losses in terms of ice mass budget. The largest type of iceberg is formed by the disintegration of massive, unconfined, seaward extending ice shelves or glacier tongues. A number of ice tongues are known to exhibit a quasi-cyclic pattern of calving and subsequent regrowth. One mechanism that would appear to explain this type of calving behavior is based on the vibrational characteristics of the system of a buoyant ice plate floating in shallow water. The glacier intercepts the ocean wave energy responsible for the motion either directly from open ocean or after transmission through, and subsequent filtering by, sea ice. The glacier also acts as a wave filter, with filtering characteristics depending on the thickness of the ice. When a

LIBRARY U. OF I., URBANA-CHAMPAIGN

dominant frequency occurring in the incident wave spectrum coincides with one of the natural frequencies of the glacier, then a resonant motion will occur. For relatively high modes of oscillation, low level but sustained cyclic bending stresses may lead to crack propagation and subsequent fatigue failure in the ice. The contributions of other mechanisms which induce tensile stresses in the ice are considered to be very important in an overall view of the calving problem, and some of these mechansism are discussed in relation to the vibration mechanism. It is possible to view the proposed vibration mechanism as a trigger which raises the resultant stresses in the ice to the point where fracture will occur. (Carroll-FRC)

RESISTANCE OF BEAUHARNOIS CANAL IN WINTER,
National Water Research Inst., Burlington, (Ontario).
G. Tsang.
Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 108, No HY2, p 167-186, February, 1982. 11 Fig, 1 Tab, 11 Ref.

Descriptors: *Canals, *Chezy equation, *Ice formation, *Flow resistance, *Electric power production, *Mannings equation, *Open-channel flow, Water management, Open channels, Roughness coefficient, Resistance, Frazil ice, Hydroelectric power, Streamflow, Ice cover.

Under natural conditions the Beauharnois Canal connecting Lake Saint-Louis and Lake Saint Francis would remain open until quite late in the winter, despite ice cover on Lake St. Francis. An open water surface invites frazil ice production, causing increased operational problems on the canal. The formation of ice cover on the canal is accelerated by placing ice booms across the canal to detain ice drift and initiate ice covers in front of them. As ice cover progresses, the resistance of the open canal to the flow changes and water resource utilization may be maximized. The flow in this canal was examined using the open-water Chezy equation while ignoring the presence of ice by using a corrective coefficient for Chezy's roughness coefficient. This corrective coefficient followed a well-defined trend during the frazil ice period which, when present in small amounts, could reduce the flow by as much as 50%. The present approach offers an advantage over using the Manning equation because it can handle situations where a river is only partially ice covered or is affected by frazil ice while avoiding a choice of formula for evaluating the composite Manning's roughness coefficient. A corrective coefficient curve was generated in the present study which may lead to an alternative ice management scheme and better electric power production on the Beauharnbois Canal. (Geiger-FRC)

A LABORATORY AND THEORETICAL STUDY OF THE BOUNDARY LAYER ADJACENT TO A VERTICAL MELTING ICE WALL IN SALT WATER,
Washington Univ., Seattle. Dept. of Oceanography.
E. G. Josberger, and S. Martin.
Journal of Fluid Mechanics, Vol 111, p 439-473, 1981. 18 Fig, 5 Tab, 23 Ref.

Descriptors: *Fluid mechanics, *Ice, Ice-water interfaces, Interfaces, Temperature effects, Salinity, Model studies, Flow, Laminar flow, *Boundry Layers, Flow characteristics.

The convection generated in the polar oceans when a freshwater ice wall melts in salt water of uniform far field temperature and salinity has been modeled in this experimental and theoretical study. The results show that there are three different flow regimes which depend on the temperature and salinity., First, when temperature and salinity lie between the maximum density curve and the freezing curve, the flow is only upward. Second, for the oceanic case where salinity lies between 30 and 35% and temperature is less than 20 degrees C, the flow consists of a laminar bidirectional flow at the bottom of the ice and a turbulent upward flow along the remainder of the ice wall. The laminar flow consists of an upward flowing layer about 2 mm thick inside of a downward flowing outer layer about 10 mm thick. Third, for the same salinity but for temperatures above 20 degree s C, the flow reverses. A laminar bidirectional flow occurs at the top of the ice above a downward turbulent flow. The governing equations were solved in similarity form with a spatially varying eddy diffusivity to model the turbulent upward flow theoretically. The spatially varying eddy diffusivity depends on the density difference between the ice/water interface and the far field. Data then allows the evaluation of the dependence of eddy diffusivity on temperature and salinity. The magnitude of the eddy diffusivity is of the same order as the molecular viscosity, and both mass injection at the interface and opposed bouyancy forces must be included in a realistic flow model. An intergral approach was used to predict the far field conditions that yield the high temperature flow reversal and obtain a result consistent with the observations. (Baker-FRC)

CONTROLLED NUCLEATION AND QUASI-ORDERED GROWTH OF ICE CRYSTALS FROM LOW TEMPERATURE ELECTROLYTE SOLUTIONS,
Lyon-1 Univ., Villeurbanne (France). Lab. de Physique des Materiaux.
J. Dupuy, J. F. Jal, C. Ferradou, P. Chieux, and A. F. Wright.
Nature (London), Vol 296, No 5853, p138-140, March 11, 1982.

Descriptors: *Ice formation, *Nucleation, Chemistry of precipitation, Precipitation, Chemical reactions, Ice, Ice crystals, Electrolytes, *Temperature effects, Controlled nucleation.

The crystallization of water was carried out in conditions where the growth is extremely slow and the nucleation events can be controlled. Slow nucleation conditions were obtained by choosing a concentration of water in an electrolyte solution such that the homogeneous nucleation temperature lay very close to the glass transition temperature. Solutions of 10.5 mo1% lithium chloride in deuterium oxide were prepared in controlled conditions to avoid the ingress of any light water. Samples of the solution were introduced into a 3-mm space between sapphire windows in a cell whose temperature could be manipulated by a controlled temperature block in which the cell was mounted. The block with cell was then suspended in a liquid helium cooled cryostat which provided the low temperature ambient for the temperature control system. Considering the mean separated crystallite size of 700 Angstroms, it was noted that the nucleation density at 139 degrees K must be a least 2,500 centers per cube micron, so high that the homogeneous nature of the nucleation phenomenon under study could not be doubted. A Guinier plot of the high Q side of the peak yields an average crystallite size for the small particles, after initial development at 140.4 K, of about 100 Angstroms. A maximum particle radium was determined of 220 Angostroms. An average radium of 100 Angostroms seems reasonable. The scattering cross section per mole of solution decreases rapidly with increasing concentration of LiC1. If the scattering power of ice initially formed from the supersaturated solution is weaker than that of the initial solution then, as the ice precipitates and residual solution concentrates, the contrast must pass through zero, giving a scattered intensity minimum. SPECTRAL REFLECTANCES OF FRESHWATER ICE AND SNOW FROM 340 THROUGH 1100 NM,
S. J. Bolsenga.
PhD Thesis, 1981. 163 p, 59 Fig, 38 Ref, 2 Append. University Microfilms International, Ann Arbor, MI; Order No. GAX81-25073.

Descriptors: *Ice, *Ice cover, *Snow, Snow surveys, *Remote sensing, Computer programs, Prediction, *Spectral reflectance, Spectroradiometers, Great Lakes, Instrumentation.

A scanning, dual spectroradiometer system which simultaneously records incident and reflected flux in the 280-1100 nm range was developed for this study. In addition, two programs were written for data acquisition and storage that are compatible with a desk-top calculator. The assemblage represents a state-of-the-art system which can be used in the laboratory, where varying incident illumination or natural light might occur, as well as in the natural environment, where changes in incident flux cannot be controlled. Several devices were fabricated to protect the instruments in the natural environment. One of the most productive uses of the scans is in ice formation, growth and decay prediction using energy budget techniques. Knowledge of the spectral reflectances of each ice type should enable the energy budget modeler to calculate the overall spectral reflectances of an ice field by first determining the ice types and amounts present in the field and then by assigning the appropriate spectral reflectances to each ice type in proportion to its areal extent. The scans for snow have provided definite spectral signature information. It appears likely that a remote sensing plan, using an aircraft under overcast skies, could be developed to distinguish between snow and clear ice on the bases of detector output alone. Since the resolution of such a system would be high, shapes of the ice types could likely be observed. By combining shape with spectral reflectances, it is possible that groups of secondary ice types could be mapped. (Sinha - OEIS)

CONFIGURATION OF ICE IN FROZEN MEDIA,
Cold Regions Research and Engineering Lab., Hanover, NH.
S. C. Colbeck.
Soil Science, Vol 133, No 2, p 116-123, February, 1982. 11 Fig, 9 Ref.

Descriptors: *Ice formation, *Crystal growth, *Frozen ground, Soil porosity, Ice-air interfaces, Pore water, Ground ice, Interstitial ice, Freezing.

Many different ice shapes and crystal distributions were detected by microscopic examination of 0.8 and 3 mm glass beads and silica sand, simulating different soils. Initial water content was 5%. Samples were examined soon after freezing and 10 months later. The air-ice interfaces were convex, and some pores were filled while others were not. Generally, small pores filled first. The variety in growth rates, nucleation sites, and local paths of heat and mass flow produced single and multicrystalline structures. Multi-crystals were common with the 3 mm glass beads, and single crystals were

more common in 0.8 mm glass beads. A variety of crystals were seen within a single sample. (Cassar-FRC)

DIRECT SNOW-WATER EQUIVALENT MEASUREMENTS BY AIR-BORNE GAMMA-RAY SPECTROMETRY,
Geological Survey of Canada, Ottawa (Ontario).
R. L. Grasty.
Journal of Hydrology, Vol 55, No 1/4, p 213-235, 1982. 10 Fig, 4 Tab, 23 Ref.

Descriptors: *Snow water equivalent, *Radioactivity techniques, Aircraft, Soil moisture, *Gamma radiation, Spectrometry, Potassium radioisotopes, *Remote sensing, Canada, *Ontario.

Snow water equivalent was measured by a technique that uses the buildup of scattered gamma-radiation from K40 with increasing snow water equivalent. This direct, single-flight airborne technique eliminates the problems associated with the standard two-flight technique, which requires soil moisture measurements, a pre-snow flight, and the same path for both flights. Variations in the gamma ray spectral shapes of K, U, and Th were determined on large concrete pads with known concentrations of the three radioelements using plywood sheets to simulate snow water equivalent layers. The airborne system was calibrated by flying over the Breckenridge and Lake Mead test areas, where radioactivity is well-documented, and converting the aircraft altitudes to an equivalent layer of water. Nine test flights over an area of unknown radioactivity 40 km southeast of Ottawa at altitudes of 90 to 210 meters gave results (141.9 + or - 13,9 mm) consistent with ground measurements of snow water equivalent (142 + or - 11 mm) and results from the two-flight method (139 + or - 1.4 mm). WINTER HEAT BUDGET AND FRAZIL ICE PRODUCTION IN THE UPPER ST. LAWRENCE RIVER,
Clarkson Coll. of Technology, Potsdam, NY. Dept. of Civil and Environmental Engineering.
H. T. Shen, and R. W. Ruggles.
Water Resources Bulletin, Vol 18, No 2, p 251-257, April, 1982. 7 Fig, 10 Ref.

Descriptors: *Frazil ice, *Heat budget, *Ice formation, *St. Lawrence River, Rivers, Ice cover, Temperature effects, Heat transfer.

Winter heat budget and frazil ice production in the St. Lawrence River between the Ogdensburg-Prescott Boom and the Moses-Saunders Power Dam were analyzed. Heat budgets and spatial distribution of heat exchange rates were calculated for three winters. The most dominant factor in the heat budget was thermal energy contained in the flowing river water. In 1974-75, a warm winter, the ice-covered period was short, large open water areas existed, and water temperature was relatively warm. Surface heat loss was relatively large. Bed heat influx and frictional heating accounted for 18% and 2% of the total heat budget respectively. Frazil ice production was not extensive. In the average winter of 1977-78 ice cover was extensive. Although the total net heat exchange was small, frazil ice production in open water areas was large. During the cold winter of 1978-79 open water areas were greater than in 1977-78 and air temperatures were lower. Frazil ice production was extensive and formed a large hanging dam at Cardinal. Predictions that there should be less frazil ice production downstream of the Iroquois dam in 1978-79 than in 1977-78 were confirmed by field studies. (Cassar-FRC)

EFFECT OF ASHFALL ON SNOWMELT RATE AT PARADISE, MOUNT RAINIER, WASHINGTON,
University of Puget, Tocoma, WA. Dept. of Physics.
B. E. Brown.
Journal of Geophysical Research, Vol 87, No C2, p 1347-1350, February 20, 1982. 1 Fig, 1 Tab, 6 Ref.

Descriptors: *Snowmelt, *Volcanoes, Temperature effects, Thaw, Paradise, Mount Rainier, Washington, Geophysics.

Paradise, Mount Rainier, was the location of the only regularly reporting weather station receiving an ashfall from Mt. St. Helens which still had significant winter snowpack on the ground, making it possible to assess the effect of a layer of volcanic ash on a mountain snowpack. Paradise is located 74km north-northeast of Mt. St. Helens, at a bearing of 27 degrees east of north from the latter peak. Paradise received an ashfall of 0.0032 to 0.0064 meters on May 18, 1980. The ashfall was very effective in accelerating the melting of the spring snow cover. Similar effects on adjacent glaciers should have produced increased runoffs during the summer of 1980. The dark ash layer increased snowmelt by about 40% over the rate which would have been expected based on ambient temperatures. (Baker-FRC)

2D. Evaporation and Transpiration

A FLOODPLAIN STORAGE MODEL USED TO DETERMINE EVAPORATION LOSSES IN THE UPPER YOBE RIVER, NORTHERN NIGERIA,
CBA Engineering Ltd., Vancouver (British Columbia).
C. D. Sellars.
Journal of Hydrology, Vol 52, No 3/4, p 257-268, July, 1981. 5 Fig, 6 Ref.

Descriptors: *Flood plains, *Evaporation rate, *Water storage, Water loss, Mathematical models, Simulation analysis, Rivers, *Nigeria, *Upper Yobe River.

The Upper Yobe River system comprises the Hadejia and Jamaare Rivers, which rise in the Jos Plateau of northern Nigeria and combine in the lowlands upstream of the town of Gashua to form the Yobe River, which flows into Lake Chad. The catchments of these three rivers were studied to determine the most effective way of developing the water resources of the basin with emphasis on larger-scale water storage and irrigation development. The flow losses in the lowland area upstream of Gashua generally amount to about 70 percent of the total annual runoff from the upland area, while losses at lake Chad approach 90 percent. The annual flow regime is seasonal, with widespread flooding in the lowland areas where the rivers are multichannel and deltaic in nature. The storage effect resulting from the formation of large open water areas and swamps in the wet season causes flooding to continue into the dry season, when potential evaporation is at a maximum. The open-water and swamp evaporation losses could not be calculated directly due to the scarcity of data on the area flooded, which varies monthly and seasonally. A flood plain storage model was developed to simulate the changes in the flooded area with time on a monthly basis for 11 years of record. The open-water and swamp evaporation losses were found to comprise about 65 percent of the total annual losses, or about 45 percent of the total runoff. Other losses included an estimated 25 percent by evapotranspiration from the shallow groundwater table in the flood plain and about 10 percent by regional groundwater flow away from the flood plain. EVAPORATION AT A HIGH ARCTIC SITE,
McMaster Univ., Hamilton, (Ontario). Dept. of Geography.
P. Marsh, W. R. Rouse, and M.-K. Woo.
Journal of Applied Meteorology, Vol 20, No 6, p 713-716, 1981. 3 Fig, 10 Ref.

Descriptors: *Arctic, *Evaporation rate, Polar regions, *Model studies, Soil water, Moisture, *Lysimeters, *Comparison studies.

This note attempts to define an empirical relationship between the alpha' parameter in Priestley and Taylor's version of the combination model and the surface soil moisture for a typical high arctic site. A comparison with the results obtained in other similar studies is also presented. The study was carried out about 5 km northeast of Resolute Airport, Northwest Territories. The dominant surface materials range from gravels to sandy loam. The climate is typical of the central Canadian High Arctic. The active layer deepens very rapidly as soon as the ground becomes bare of snow. To allow the direct measurement of evaporation small lysimeters were used which measured 13.8 cm in depth and 9.8 cm in diameter. The measured evaporation rates varied depending on the site of the lysimeter. For soil moisture volumes greater than 30% evaporation is large and proceeds near the potential rate. Between 30 and 20% there is a very rapid decrease in evaporation and below 20% it is very small. It was apparent from the study that there is no unique relationship between surface soil moisture and evaporation rates. The unvegetated high arctic soils are distinctive because it is the surace layer that must provide the water for evaporation, a major flux from deeper layers being unlikely due to the cold permfrost zone. As a result the evaporation rate falls rapidly as the soil surface dries. Most sites are distinctive, and under drying conditions the evaporation rate will be a response to the particular site characteristics. A generalized model is unlikely to be achieved. (Baker-FRC)

EVALUATION OF THE EFFECT OF LINEARIZATION OF THE MAGNUS EQUATION ON THE ACCURACY OF CALCULATING EVAPORATION FROM THE SURFACE OF MOIST SOIL AND TRANSPIRATION,
Akademiya Nauk SSSR, Moscow. Inst. Vodnykh Problem.
E. A. Lozinskaya.
Water Resources, Vol 8, No 2, p 114-119, March-April, 1981. 3 Fig, 6 Ref. Translated from Vodnye Resursy, No 2, p 50-55, March-April, 1981.

Descriptors: *Soil-water-plant relationships, *Specific humidity, *Evapotranspiration, Magnus equation, Linear equation, Mathematical equations, Evaporation, Soil water, Transpiration, Humidity, Air temperature, Temperature, Vegetation effects.

The Magnus equation, one of four in a system used to calculate evaporation from the surface of moist soil, relates the saturated specific humidity of air to its temperature. Linearization of this equation produces less accurate results but clearly shows the relation between evaporation and various parameters of the problem. It is also more graphic and convenient for practical use. Errors introduced into the evaporation determination by linearization did not exceed 3% in typical cases and 8% in extreme cases. LIBRARY U. OF I.- URBANA-CHAMPAIGN

Three studies were performed by United Engineers and Constructors Inc... (UE and C) and Versar, Inc. to aid EPA in assessing water consumption and other nonwater quality environmental impacts of cooling systems used by the steam-electric generating industry. The two reports on water consumption agree that the Leung-Moore model satisfactorily predicts evaporation rates of evaporative cooling towers. Versar found that this model predicted evaporation rates of base-load plants within + or - 15 percent of material balance values based on plant data. UE and C addressed the Harbeck and Brady models for predicting evaporation rates from cooling ponds and (using available data) could not reach a definite conclusion on which model predicted evaporation more closely. Comparing predictions from five models, including the Harbeck and Brady models, Versar concluded that the Harbeck-Hughes and Meyer models predicted evaporation rates for five of six cooling ponds studied within + or - 15 percent of material balance values and appear suited to preliminary studies. UE and C conclude that limited data precluded general conclusions on drift effects from saltwater cooling towers, but that cooling tower drift and deposition apparently do not increase ambient salt loading to an extent that a significant impact has been observed or is expected. Similarly, the effect of wet cooling tower and stack plume interactions on acid rain formation and deposition could not be established from available information. (Moore-SRC)

INFLUENCE OF SEASONAL EVAPORATIVE DEMAND ON EVAPOTRANSPIRATION AND YIELD OF IRRIGATED WHEAT,
Jawaharlal Nehru Agricultural Univ., Jabalpur (India). Dept. of Soil Science and Agricultural Chemistry.
I. K. Jaggi, and S. B. Sinha.
Indian Journal of Agricultural Sciences, Vol 51, No 12, p 891-895, December, 1981. 3 Fig, 2 Tab, 6 Ref.

Descriptors: *Irrigation, *Evapotranspiration, *Water use efficiency, Soil-water-plant relationships, *Wheat, Crop yield, Grain crops, *India.

Irrigated wheat (Triticum aestivum Linn. emend. Thell.) was grown in India during 2 successive winter seasons to determine the seasonal variations in extractable soil water in a meter profile, evapotranspiration, and evaporative losses from an open pan. Extractable soil water remained between 13 and 18 cm for the first 90 days in both seasons, indicating that the evapotranspiration needs of the wheat were largely met by irrigation or rainfall. By day 120 extractable soil water had reached less than 4 cm. The second season had less rainfall, slightly lower amounts of extractable soil water, and a greater open pan evaporation rate. Evapotranspiration was 35.9 cm in both seasons, of which 1/3 was contributed by profile-stored water. Open pan evaporation rates were 1 to 5 mm per day the first season and 2 to 8 mm per day the second season. Grain yields were 44.1 q per ha the first season and 40.2 q per ha the second, drier season. Water use efficiency (in q per ha per cm) was 1.23 the first season and 1.11 the second. On this vertisol the optimum yield of irrigated wheat may be predicted for a season with evapotranspiration/open pan loss ratios from 0.7 to 1.1. Serious yield reductions are likely at ratios below 0.6. (Cassar-FRC)

STABILITY EFFECTS ON GREAT LAKES EVAPORATION,
National Oceanic and Atmospheric Administration, Ann Arbor, MI. Great Lakes Environmental Research Lab.
J. A. Derecki.
Journal of Great Lakes Research, Vol 7, No 4, p 357-362, 1981. 6 Fig, 2 Tab, 9 Ref.

Descriptors: *Lakes, *Evaporation, *Lake evaporation, Water loss, Great Lakes, Atmosphere, Atmospheric physics, Atmospheric pressure, Stability analysis, Mathematical studies, *Lake Erie, *Lake Superior, *Lake St Clair.

This paper summarizes air stability effects on evaporation for the highest and lowest Great Lakes in terms of evaporation, Lakes Superior and Erie, and also for a much smaller water body within the chain of Great Lakes, Lake St. Clair. Stability effects for the other, intermediate Great Lakes should fall between these extremes. The mass transfer method for computing evaporation is based on the removal of water vapor from the lake surface by turbulent diffusion. It is a function of the overlake wind speed and the vapor pressure difference between the saturated air at the lake surface and the ambient air at some predetermined level. The results indicated that atmospheric stability has to be considered for reliable mass transfer evaporation estimates from the Great Lakes. Seasonal variation in the mass transfer coefficient was seen to be of similar magnitude to that of the input data (wind, vapor pressure difference) or evaporation, and the use of constant coefficients cannot be justified. Winter ice-cover reduction of evaporation was seen to be perhaps as important as the stability effects on the input data or mass transfer coefficient and should be included for lakes with extensive ice cover. It was also noted that inclusion of the air stability-dependent mass transfer coefficient, land to lake data adjustment, and ice-cover effects during winter permits determination of realistic mass transfer operational evaporation estimates from readily available perimeter data. ESTIMATION OF ISOTOPIC EXCHANGE PARAMETERS, USING CONSTANT-FEED PANS,
Commonwealth Scientific and Industrial Research Organization, Glen Osmond (Australia). Div. of Soils.
G. B. Allison, and F. W. Leaney.
Journal of Hydrology, Vol 55, No 1/4, p 151-161, 1982. 4 Fig, 2 Tab. 12 Ref.

Descriptors: *Evaporation pans, *Isotope studies, Water vapor, Humidity, Lakes, Measuring instruments, Isotope fractionation, Air-water interface, Evaporation.

Constant volume evaporation pans were used to estimate the isotopic composition of water evaporating from an open water body. There was close agreement between directly measured values and the values estimated from the pans for the isotopic composition of water vapor in the atmosphere and the relative humidity of the air normalized to the water surface temperature. To obtain annual data, separate experiments should be run for each 2-3 month period to avoid large climatic changes within the time scale of each experiment. This information is expected to be useful in water balance studies of open water bodies. (Cassar-FRC)

A PREDICTION EQUATION FOR DAY NIGHT WIND RATIO CORRECTION ON REFERENCE CROP EVAPOTRANSPIRATION,
Marathwada Agricultural Univ., Parbhani (India).
G. R. Rao, S. L. Tate, and S. B. Varade.
Annals of Arid Zone, Vol 20, No 3, p 199-201, 1981. 2 Fig, 2 Ref.

Descriptors: *Evapotranspiration, *Semiarid lands, *Water requirements, Wind, *India, Penman equation, Monsoons.

Reference crop evapotranspiration (ET) values predicted by the modified Penman equation are corrected for day/night wind ratio under Indian conditions by the following equation: ETo = 0.969 + 0.812ETo*, where ETo and ETo* are the adjusted and unadjusted reference crop ET in mm per day, respectively. Unadjusted values (ETo*) are near to adjusted ET values after establishment of the southwest monsoon (late summer-fall), close or underpredicted in winter, and overpredicted in the premonsoon season (spring and early summer). The day/night wind ratio (range 1.1 to 3.8) is highest after establishment of the monsoon and lowest in the premonsoon season. (Cassar-FRC)

MEASUREMENT AND MODELLING OF PRIMARY PRODUCTION AND WATER USE IN A SOUTH TUNISIAN STEPPE,
Centre National de la Recherche Scientifique, Montpellier (France). Centre d'Etudes Phytosociologiques et Ecologiques Louis-Emberger.
C. Floret, R. Pontanier, and S. Rambal.
Journal of Arid Environments, Vol 5, No 1, p 77-90, 1982. 5 Fig, 2 Tab, 31 Ref.

Descriptors: *Water use, *Steppes, Grasslands, Evaporation, Tunisia, Natural use, Model studies, Water resources development, Water supply development, Plant populations.

The effect of rainfall on above ground plant production was studied between 1971 and 1977 on a site consisting of steppeland on sandy soil, dominated by the perennial dwarf shrub Rhantherium suaveolens, with associated annual species. The average precipitation in this region was 180 mm, which produced about 1000 kg of dry matter/ha. A model was developed, ARFEJ, using the most pertinent characteristics of the system so that production could be predicted under the assumption that water is the limiting factor. Seven model coefficients were calculated with data from 1971-1975. The results of this study indicate that the effect of rainfall distribution on evaporation from bare soil is extensive. The mean of this evaporation was 55% of total evapotranspiration. During the short annual period of fast growth, the ratio of dry matter to water transpired would be about 1.26 g dry matter/kg water for annuals and 1.39 g dry matter/kg water for perennial species. Over the whole year, the average efficiency of water use was 0.45 g dry matter/kg water for all species. Above 250 mm of precipitation, the availability of nitrogen and/or phosphorus became the limiting factor for plant production, and efficiency of water use decreased. The accuracy of growth trends in general indicated that the model had considerable predictive value. It is therefore possible to calculate not only the dynamics of the phytomass of annual and perennial species, but also variations in soil water content. The model could help in range management by forecasting carrying capacity consistent with plant production, the quantity of fodder reserves needed and the time when they must be available. DOWNSTREAM REDUCTION OF RURAL CHANNEL SIZE WITH CONTRASTING URBAN EFFECTS IN SMALL COASTAL STREAMS OF SOUTHEASTERN AUSTRALIA,
Wollongong Univ. (Australia). Dept. of Geography.
G. C. Nanson, and R. W. Young.
Journal of Hydrology, Vol 52, No 3/4, p 239-255, July, 1981. 32 Ref.

Descriptors: *Channel flow, *Coastal streams, Flood plains, Urban planning, Land use, Flood discharge, Alluvial channels, *Australia, *New South Wales, *Urban effects, Coastal streams, *Channel morphology.

Although the size of a river channel normally relates to the volume of water the channel must carry, streams flowing off the Illawarra escarpment in New South Wales, Australia, show a marked reduction of channel size accompanied by a downstream increase in flood frequency in their lower reaches. Bed and bank sediments are relatively coarse and uncohesive in the confined and steeply sloping valleys of the escarpment foothills, and channels increase in size in relation to increasing discharge downstream. However, there is a dramatic reduction in channel size as these streams emerge into the more open rural valleys at lower

slopes which are accompanied by extensive floodplains formed of fine cohesive sediment. The sudden decline in channel slope and associated stream power, the cohesive nature of the downstream alluvium, retention of the sediment on the channel banks by a dense cover of pasture grasses, and the availability of the extensive flood plain all contribute to the decrease in channel size. Floodwaters from these streams very frequently spill out over the floodplain, resulting in the reduction of the downstream channel flow to a relatively minor component of the total peak discharge. Stream channels formed in the fine alluvium rapidly entrench and increase in cross-sectional area by two to three times when urban development results in increased peak runoff and decreased effective floodplain area. This enlargement may be triggered by minor human-induced channel alteration and maintenance. (Carroll-FRC)

STABLE-CHANNEL DESIGN IN GRAVEL-BED RIVERS,
Ministry of Works and Development, Christchurch (New Zealand).
G. A. Griffiths.
Journal of Hydrology, Vol 52, No 3/4, p 291-305, July, 1981. 2 Fig, 4 Tab, 27 Ref.

Descriptors: *River beds, *Gravel, *Stable channels, Mathematical equations, Particle size, Sediments, Sediment load, Mathematical models.

Regime relations are derived for more or less straight, stable, symmetrical, wide reaches of coarse gravel-bed rivers having low rates of bedload transport and at bankfull flow conditions. The relations are combined to express channel width as a function of median size of bed pavement, energy slope, and bankfull water discharge for sediment of constant specific gravity. This stable-channel design equation, together with three others of similar form in current usage, is tested for accuracy of channel with prediction with 60 field data sets from appropriate gravel-bed reaches. The minimum mean deviation of predicted width from the actual width prescribed in each data set was 160 percent, with a standard deviation of 430 percent. A dimensionless stability index, defined in terms of the above parameters, is deduced and shown to be remarkably constant in value at stable reach sections on particular gravel-bed rivers and for rivers within a single watershed. Employment of this index will result in a substantial improvement in the accuracy of stable-channel design. The range of application of the stability index method is increased by combination with an empirical equation that predicts median bed-pavement size from given flow conditions over gravel-bed material having a known initial sediment size distribution. An example of the suggested design procedure following from this combination is given for an existing unstable river-diversion channel. Some recommendations are made concerning the identification of stable river reaches and the determination of the requisite sediment parameters for design. (Author's abstract-FRC)

THE RELATIONSHIP BETWEEN FLOW-SHEAR STRESS AND STREAM PATTERN,
Geological Survey of Israel, Jerusalem.
Z. B. Begin.
Journal of Hydrology, Vol 52, No 3/4, p 307-319, July, 1981. 5 Fig, 1 Tab, 24 Ref.

Descriptors: *Shear stress, *Streams, *Stream profiles, Stream discharge, Braided streams, Data interpretation, Mathematical equations, *Hydrological regime, Geologic environment.

River channel patterns, whether straight, meandering, or braided, represent an equilibrium between hydrologic regime and geologic environment. Previous studies have shown that channel pattern is related to stream power, and therefore to hydraulic parameters which describe the flow in a more meaningful way than the mere specification of a certain combination of slope and discharge. The purpose of this study is to present a physical interpretation of the relationships depicted on a discharge-slope diagram which can be used to rationally differentiate between braided, straight, and meandering streams. Simple hydraulic reasoning is used to assign a 'relative shear-stress' value to each stream on the basis of a discharge-slope diagram for streams. A sample of 359 streams, ranging in mean annual discharge from 900,000 to 0.05 cubic feet per second and varying in pattern from highly sinuous to straight and braided, is sorted according to relative shear-stress values. Straight streams are produced by low-energy flow. Increases in energy, which are also increases in shear stress, result in bank erosion and meandering due to internal instability of the flow, which produces secondary currents. When an additional increase in flow energy results in such a high momentum that a different equilibrium is maintained between flow and bank sediments, the streams tend to have a greater radius of curvature of bends and to be less sinuous. A further increase in shear stress will result in such a high rate of bank erosion and sediment transport that braided channels form. The passage from one pattern to another within natural stream populations is gradual, since the geomorphic thresholds, defined by relative shear stress, tend to be fuzzy. (Carroll-FRC)

A STUDY OF LOW-FLOW OPERATION OF MILFORD AND ELK CITY LAKES IN KANSAS,
Kansas Water Resources Research Inst., L Manhattan.
Y-S. Yu, E. C. Pogge, V. Knapp, and S. Esmaeil-Beik.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224536, Price codes: A13 in paper copy, A01 in microfiche. Contribution No 217, October, 1980. 280 p, 75 Fig, 61 Tab, 62 Ref. OWRT B-053-KAN(1). 14-34-0001-8087.

Descriptors: *Streamflow, *Time series analysis, Lake evaporation, Mass-transfer method, Mathematical models, Reservoir operation, *Dynamic programming, Stochastic processer, Kansas, Elk River, Milford Lake, Low flow, Synthetic hydrology, Simulation analysis.

PART I -- The streamflow records at Elk City, Kansas, on the Elk River and at Clay Center, Kansas, on the Republican River have been analyzed to determine the seasonal means, standard deviations, correlation coefficients and skew coefficients. A first-order Markovian model has been developed for generating the synthetic streamflows. This model generates weekly and monthly streamflows, respectively, for the Elk River and the Republican River. The results indicate that taking the square root of the observed series prior to the application of the model produces the best overall agreement between the stochastic parameters of the synthetic streamflows and those of the observed streamflow series. PART II -- Weekly evaporations from the Milford and Elk City Lakes, respectively, were computed based on available climatological data, measured water temperature and the mass-transfer equation. The mean annual evaporations obtained from the weekly values for the Milford and Elk City Lakes are about 3% and 9%, respectively, greater than the values presented in the U. S. Weather Bureau Technical Report No. 37 (1959). The monthly pan coefficients obtained from this study are generally 5% higher than the pan coefficients used by the Kansas Water Resources Board (1974). Mathematical models for weekly evaporation were developed by the combined use of the Fourier approximations and an autoregressive model. The generated time series of the weekly evaporation closely matches the statistics of the weekly evaporation computed by the mass-transfer method. A sensitivity analysis was also made to determine the effect of variation of the model parameters on estimated evaporation and the change of evaporation per unit change of each input component of the mass-transfer equation. The results show that the mass-transfer model is most sensitive to changes in the water temperature. Part III -- A stochastic dynamic programming model has been developed and applied to determine the steady-state optimal policies for operating the conservation storages of Elk City and Milford Lakes, respectively. The model for the smaller Elk City Lake is based on Weekly net inflows calculated from the historical data while the model for the larger Milford Lake is based on monthly net inflows. The derived optimal policies are applied to operate the respective reservoir over a period of 10 years from 1967 through 1977. The results show that the developed algorithm is efficient in terms of both computer storage and time, attributable to the adaptation of a termination criterion based on the method of successive approximations. The results also show that adopting the optimal policies in operating the reservoir results in substantially less deviations from target storage than those shown in historical record.

DERIVATION OF HOMOGENEOUS STREAMFLOW RECORDS FOR THE GREEN RIVER BASIN, KENTUCKY,
Geological Survey, Doraville, GA. Water Resources Div.
T. W. Hale.
Geological Survey Open-File Report 79-1066 (WRI), 1979. 61 p, 39 Fig, 4 Tab, 5 Ref.

Descriptors: *Streamflow forecasting, Rivers, *Reservoirs, *Computer models, Simulation analysis, Hydrologic data, Low flow, Natural flow, Regulated flow, Routing, Reservoir operation, *Kentucky, *Green River basin.

Four flood-control reservoirs, Green River Lake, Nolin River Lake, Barren River Lake, and Rough River Lake, were completed in the Green River basin of Kentucky between 1959 and 1969. A digital computer model of these reservoirs and the stream reaches from the reservoirs downstream to the Green River at Calhoun, Ky., was developed to simulate mean daily streamflows. Simulations of 1941 through 1971 water year streamflows were made for both the pre-reservoir and post-reservoir basin conditions, thus supplying homogeneous data sets for low-flow analyses of eight stream sites. The 7-day, 10-year recurrence interval, minimum discharges of the simulated regulated flows exceed those of the simulated natural flows by about 30 cubic feet per second for the Barren River at Bowling Green, Ky., and about 260 cubic feet per second for the Green River at Calhous, Ky. Analyses of the pre-reservoir simulations show that, for seven of the stream sites, the model yields streamflow which have annual minimum 7-day average discharges that are not significantly different, at the 95 percent significance level, from those of the observed flows. Results of the post-reservoir simulations show that actual reservoir operation was not closely matched by the model. Therefore, the low-flow characteristics of the simulated regulated streamflows are merely estimates of those that could be expected if the basin were regulated according to the modeled reservoir operating criteria. Descriptors: *Streamflow, *Stream discharge, Data collections, Low flow, *Base flow, Flow characteristics, Flow measurement, Surface-groundwater relations, Aquifers, Seepage, Runoff, *New York, *Long Island, Nassau County.

South-shore streams on Long Island, N.Y., are small, widely spaced and have few or no tributaries. Their gradients are gentle, averaging 10 feet

LIBRARY U. OF I., URBANA-CHAMPAIGN

per mile. All streams in the area studied have a mean annual discharge of less than 20 cubic feet per second, and most are from 3 to 10 miles long. Under natural conditions, about 95 percent of total streamflow originates as ground-water seepage from the upper glacial aquifer; the remaining 5 percent consists of direct runoff. Thus, the streams of Long Island function as ground-water drains, the flow of which in dry weather is controlled directly by ground-water levels adjacent to the stream channels. Monthly low-flow discharge measurements of 18 south-shore streams in Nassau County from 1978-79 are tabulated in this report. Measurement sites were established at 1,000-foot intervals between the southern tide-affected reach and the northern headwaters of each stream. The measurements provide a data base for the 'Flow Augmentation Needs Study,' supported by the U.S. Environmental Protection Agency, which will evaluate the need to replace streamflow lost through lowering of the water table as a result of sewage in Nassau County Sewer Districts 2 and 3. NATURE OF WAVE ATTENUATION IN OPEN CHANNEL FLOW,
San Diego State Univ., CA.
V. M. Ponce.
Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 108, No 2, p 257-262, February, 1982. 5 Ref.

Descriptors: *Mathematical studies, *Open-channel flow, *Kinematic waves, *Waves, Wave action, Mathematical equations, Channel flow, Kinematic wave theory, Unsteady flow, Flow friction, Flow velocity, Channels, Wave velocity.

The mechanisms responsible for wave attenuation in open channel flow were studied in order to identify the term or group of terms which will cause a free-surface flow wave to dissipate. Linear stability theory was used to clarify the nature of wave attenuation in prismatic channels. Wave attenuation is shown to result from the interaction of the kinematic term (friction and bottom slope) with the local acceleration term. When local acceleration is neglected, wave attenuation may be attributed to the interaction of the kinematic term with the pressure gradient or convective acceleration terms or both. These findings may prove useful in the study of unsteady open channel flow. (Geiger-FRC)

NEW METHODS OF DESIGNING FLOOD CONTROL MEASURES,
A. V. Kozar, and Z. D. Romanyutina.
Water Resources, Vol 8, No 2, p 119-126, March-April, 1981. 2 Fig, 15 Ref. Translated from Vodnye Resursy, No 2, p 56-64, March-April, 1981.

Descriptors: *Flood control, *Reservoir releases, *Streamflow forecasting, Automation, Reservoir operation, Weather forecasting, Flood forecasting, *Stryi River, *USSR, Water storage, Control systems, Information systems, Water level recorders, Cloudbursts, Forecasting, Water management, Systems analysis, Precipitation, Rainfall-runoff relationships.

The flood control complex for the Stryi River, USSR, incorporates an automatic information measurement system for forecasting floods and controlling the hydrostation. High annual precipitation, 321 to 1301 mm, and summer cloudbursts cause catastrophic floods in this region. When heavy rainfall has been forecast, water is released from the reservoir at a rate which does not damage the downstream land. The automatic information measurement system consists of five subsystems: Short-range forecasting of rainfall floods, operative control of the hydrostation, analysis and monitoring of the control of the hydrostation, planning for multipurpose use of the water, and forecasting of water quality. Further refinements to the automated system are planned. A denser network of automatic observation posts will be installed, evaluated, and expanded if desirable. Forecasting is done by radar measurement of precipitation within a 100 km radius. This information is processed by the system to indicate the amount of moisture that fell on the drainage basin. Automated ground precipitation gages are used to double check the amount of precipitation. Water levels in the reservoir and at stream gaging stations are automatically measured. These measures are expected to reduce flood damages in this basin by 70%. (Cassar-FRC)

CONSEQUENCES AND RESPONSIBILITIES IN DROUGHT FORECASTING: THE CASE OF YAKIMA, 1977,
National Center for Atmospheric Research, Boulder, CO.
M. H. Glantz.
Water Resources Research, Vol 18, No 1, p 3-13, February, 1982. 5 Fig, 3 Tab, 51 Ref.

Descriptors: *Water allocation, *Forecasting, *Drought, *Yakima Valley, *Washington, Water supply, *Legal aspects, Political aspects, Social impact, Economic impact, Irrigation, Prediction, Water rights, Bureau of Reclamation, Streamflow forecasting, Weather modification, Columbia River basin.

In February 1977 the Bureau of Reclamation issued an erroneous forecast that during the coming irrigation season Yakima, Washington, irrigators would have an available water supply less than half of the average long-term supply. Those with senior water rights were to receive 98% of their normal water allocation; those with junior rights, 6% of their normal allocation. The forecast and allocations caused irrigation districts, farmers, and government agencies to undertake drought-inspired actions. These responses included buying and selling water rights at greatly inflated prices, constructing new wells at costs up to $250,000 each for a total of $9 million, proposing large-scale diversion projects, transplanting of mint and other perennials to the Columbia River Basin at personal expense, cloudseeding at a cost of $400,000 and complaints from states which felt their rainwater was being stolen, and implementing water conservation practices in farming. As the spring progressed it was evident that the forecast was not correct. Angry farmers started legal suits to recover some of the millions of dollars unnecessarily spent for drought protection. The primary forecasting error, since admitted by the Bureau, was a balancing out of return flow against some relatively minor diversions to other smaller irrigation projects. This should be done for flood control but not for water allocation. As a result of the fiasco the Bureau lost its credibility, built up since 1945. This raises the question of whether farmers will implement drought measures if the Bureau forecasts water shortages in the future. (Cassar-FRC)

BEND THEORY OF RIVER MEANDERS. PART 1. LINEAR DEVELOPMENT,
Saitama Univ. Urawa (Japan), Dept. of Foundation Engineering.
S. Ikeda, G. Parker, and K. Sawai.
Journal of Fluid Mechanics, Vol 112, p 363-377, 1981.

Descriptors: *Meanders, *Mathematical equations, Fluid mechanics, Rivers, Hydraulics, *Bank erosion, *Alluvial channels, Comparison studies.

In this analysis the heuristic model of Ikeda is used to develop a formal stability theory of channels with sinuous banks. Bank erosion is described, and the stability criterion is presented in terms of the growth rate of lateral bend amplitude. This aspect suggests the parlance of 'bend' theory, as opposed to the previously quoted 'bar' theories. The bend theory is applied to both the alluvial and incised cases. The linear theory herein yields a relation for initial characteristic bend wavelength that differs from that of Ikeda and shows much better agreement with data. A comparison with the predictions of one of the 'bar' theories indicates that, for alluvial streams, bar and bend instabilities operate at similar wavelengths when sinuosity is not too large. SEVERAL PLUME FLOWS IN PURE AND SALINE WATER AT ITS DENSITY EXTREMUM,
State Univ. of New York at Buffalo, Amherst. Dept. of Mechanical and Engineering Aerospace.
J. C. Mollendorf, R. S. Johnson, and B. Gebhart.
Journal of Fluid Mechanics, Vol 113, p 269-282, 1981. 4 Fig, 2 Tab, 14 Ref.

Descriptors: *Fluid mechanics, *Plumes, Flow, *Temperature effects, Salinity, Mathematical equations, Laminar flow, Physical properties, *Density, Density stratfication, Saline-freshwater interfacts.

This study is a similarity analysis of three constant-buoyancy plume flows in pure or saline water at its extremum temperature. Although the effect of saline diffusion is neglected, the influence of salinity level is retained. The analysis considers the only conditions for which a similarity solution is known for constant-buoyancy plume flows in cold unstratified water. The calculated results cover a wide range of Prandtl numbers and salinity and pressure levess. The three flow situations considered here are two above a horizontal line heat source and one above a point heat source. The first flow is a freely rising plane plume and the second is a wall plume (flow over a vertical, adiabatic surface with a horizontal line source imbedded in it). The third flow is the freely rising axisymmetric plume. These are the models in laminar theory of many processes which arise in cold water. The main purpose of the study was to calculate the effect of using a nonlinear density relation for water, which is much more accurate at low temperatures than the conventional linear one used in classical analyses. The downstream variations of the temperature and velocity fields were found to be very different from those for flows where the effect of a density extremum is not included. (Baker-FRC)

A NOTE ON THE STRUCTURE OF THE HEAD OF AN INTRUSIVE GRAVITY CURRENT,
Cambridge Univ. (England). Dept. of Engineering.
R. E. Britter, and J. E. Simpson.
Journal of Fluid Mechanics, Vol 112,p 459-466, 1981. 7 Fig, 17 Ref.

Descriptors: *Gravity studies, *Fluid mechanics, *Density currents, Water Currents, Plumes, Density, Interfaces, *Saline-freshwater interfaces.

In this note experiments are described in which the ratio of interface thickness to current depth and the ratio of current depth to the overall depth of fluid are systematically varied. The head of an intrusive flow advancing along the interface between two fluids is studied. The dependence of the flow on the interface thickness and the depth of the intrusion is determined. The tank used in the experimentation was 360 cm long by 20 cm wide and could be filled to a depth of 45 cm. It was filled to half the required depth with salt water and then tap water was carefully added to an equal depth above it. A partition was inserted 50 cm from one end, and the two fluids behind it were completely mixed. Removal of the partition released a current whose head was viewed throughout its journey by shadowgraph. The experiments show, at the smallest interfaces, clear Kelvin-Helmholtz billows, whose two-dimensional form is not broken up by any lobe and cleft structure as in boundary currents. When the interface thickness was less than 1/5 of the depth of the current, the behavior of the intrusive head approached that of a reflected inviscid current. This supports the conjecture that the results of Britter and SSimpson would be directly applicable to flows under a free surface. As the ratio of interface thickness to current depth increases, the Kelvin-Helmholtz billows were reduced in magnitude until mixing between the two fluids at the head ceases. When the interface thickness is comparable to the current depth the speed of second mode internal waves may be close to, or greater than, that of the intrusion and an interaction between the internal wave and the intrusive flow is noted. (Baker-FRC)

DISCHARGE CAPACITY OF LARGE STREAMS UNDER AN ICE COVER,
V. S. Altunin, E. G. Gladkov, and V. L. Ryabov.
Hydrotechnical Construction, Vol 15, No 6, p 329-335, June, 1981. 5 Fig, 3 Tab, 11 Ref. Translated from Gidrotektekhnicheskoe Stroitel'stvo, No 6, p 14-18, June, 1981.

Descriptors: *Ice cover, *Canal design, *Discharge capacity, Ice formation, *Flow velocity, Roughness coefficient, Rivers, Hydraulic structures, Hydraulic roughness, Design criteria, *USSR.

The effects of ice formation on the discharge capacity of large unlined canals (discharges of 500-1000 cu m per sec) were observed in several rivers in Russia during 1977-80. Equations were developed to describe the observations. Roughness coefficients do not remain constant during the ice period even in the absence of visible deformations of the canal bottom and in the presence of very small roughness projections on the lower ice surface. Mean velocity of flow has the greatest effect on the value of roughness coefficient. Rapid formation of an ice cover is desirable to minimize ice problems. Usually flow velocity is limited and average filling is maintained to encourage the formation of crystalline ice. Ice jams can be prevented by reducing releases and maintaining average filling. The long profiles of several major rivers in Maryland and Virginia are studied, and explanations for discontinuities near the Fall Line are sought. It is postulated that changes in base level during sea-level fluctuations in the Pleistocene were important contributors to discontinuities. Quarternary downcutting in response to a lowered base level may exlain the process. Strong circumstantial evidence suggests that the discontinuities in river profiles may be due to differential uplife of the Piedmont as well. However, terrace remnants at higher elevations are so dissected that correlations between remnants is impossible. Also, no fossils or radiometrically datable materials have been recovered from terraces above the Fall Line, and attempts to apply paleomagnetic techniques have yielded equivocal results. (Titus-FRC)

STOCHASTIC ANALYSES AND TRANSFER FUNCTIONS FOR FLOWS OF THE UPPER DELAWARE RIVER,
Rutgers - The State Univ., New Brunswick, NJ. Dept. of Chemical and Biochemical Engineering.
R. C. Ahlert, and B. M. Mehta.
Ecological Modelling, Vol 14, No 1, p 59-78, 1981. 5 Fig, 13 Tab, 10 Ref.

Descriptors: *Stochastic process, *Model studies, *Flow discharge, Water supply systems, Mathematical models, *Delaware River, Streamflow.

The use of stochastic modeling for description of regulated and unregulated flows and coupled flow networks is described, and application of this methodology to surface flows for the upper Delaware River and its tributary, the Lehigh River, is demonstrated. This type of modeling is possible only when data are available for extensive time periods and at relatively uniform intervals. Autoregressive integrated moving average (ARIMA) models have been synthesized to describe the random components of discharge time series. The effects of reservoir control on predictive flow models are examined in the context of combined deterministic-probabilistic models. Transfer functions have been developed to model the interaction between input and output data without a deterministic structure. Cross-correlation analysis has been used to describe the propagation of chance events throughout the system. (Carroll-FRC)

HYDROLOGIC ANALYSIS OF PEARL RIVER FLOODS, APRIL 1979 AND APRIL 1980, IN LOUISIANA AND MISSISSIPPI,
Geological Survey, Baton Rouge, LA. Water Resources Div.
F. N. Lee, and G. J. Arcement.
Louisiana Department of Transportation and Development Research Study No 81-1-SS, 1981. 37 p, 40 Fig, 4 Tab, 19 Ref.

Descriptors: *Floods, *Flood peak, Precipitation, Streamflow, Runoff, Excess rainfall, Frequency analysis, *Flood data, Flood damage, Urbanization, *Louisiana, *Mississippi, *Pearl River.

Double-mass and trend curves of precipitation and streamflow data indicate that flooding in the Pearl River basin follows a natural, random pattern. The April 1979 flood was caused by excessive rainfall in the upper part of the basin where as much as 19.6 inches of rain fell in one storm. This caused the largest flood since 1901 in the Jackson, Miss. area, and the largest since 1938 in the Bogalusa, La. area. The Ross Barnett Reservoir, although generally not having a measurable effect on flood peaks in the Bogalusa area, may have dampened the peak discharge of the April 1979 flood in the Jackson, Miss., area by as much as 20%. The April 1980 flood was caused by excessive rainfall over the entire Pearl River basin, where precipitation amounts ranged from 8.6 to 15.0 inches. The coincidental timing of peak discharges of the Pearl River and the Bogue Chitto at their confluence caused a larger flood peak to occur near Slidell, La. than would be expected, based on the peak discharge recorded at Bogalusa, La. Land-use statistics indicate that about 4.8% of the basin is urbanized. Damage to urban property during the April 1980 flood amounted to about 12.75 million dollars in the Slidell area alone. (USGS)

S. D. Waltemeyer, and R. R. Shields.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-185760, Price codes: A05 in paper copy, A01 in microfiche. Geological Survey Water-Resources Investigations 81-82, March 1982. 74 p, 1 Fig, 5 Ref.

Descriptors: *Streamflow, *Stream discharge, *Discharge frequency, *Data collections, Flow characteristics, Gaging stations, regulated flow, Low flow, Flow duration, Flood frequency, *Montana, *Upper Columbia River basin.

Statistical summaries of streamflow data for selected stream-gaging sites presented in this report aid in appraising the hydrology of the upper Columbia River basin in Montana. Streamflow records are provided for 54 gaging stations for the period of record. Streamflow records for five gaging stations were compiled into separate periods related to changes in regulation after data collection commenced. The entire period of record, the period before regulation, and the period after regulation are presented for comparison. For each gaging station selected for this report, a brief description is given for station location, drainage area, period of record, revisions of previously published records, type and history of gages, regulation and diversions, and extremes of discharge. These data are followed by tables of monthly and annual flow statistics, flood-frequency data, low-flow and high-flow frequency data, and flow-duration information. (USGS)

Available from the Br. of Distr. 1200 S. Eads St. Arlington, VA 22202, Price: $14.00. Geological Survey Hydrologic Investigations Atlas HA-653, 1981. 7 Sheets, 7 Ref.

Descriptors: *Floods, *Flood damage, Precipitation, Storm runoff, *Flood discharge, Flash floods, Flood plains, Flood recurrence interval, Flood profiles, Aerial photographs, *Wisconsin, *Kickapoo River, Flood-plain delineation.

The Kickapoo River valley in southwestern Wisconsin had a devastating flood ($10 million estimated damages) during July 1-5, 1978. The flash flooding was caused by intense storms on June 30 through July 2. Total rainfall accumulation ranged from 5.8 inches near Ontario to 9.5 inches at La Farge. The resulting flood equaled or exceeded the largest ones recorded since the 1850's and equaled or exceeded the 100-year flood frequency at the U.S. Geological Survey's streamflow gages at La Farge and Steuben. Elevation and delineation of the flood are shown on photo mosaics developed from black and white aerial photographs. The 100-mile reach from Wauzeka to Wilton is shown. A summary of the storm conditions causing the flood and an analysis of the rainfall totals, as prepared by the Wisconsin Geological and Natural History Survey, are also included. (USGS)

Descriptors: *Flood peak, *Estimating equations, Prediction, Mathematical equations, Regional analysis.

Most hydrologic design problems occur at sites for which stream-gage data are not available. Either an uncalibrated estimation method or an empirical equation based on a regionalization of peak discharge estimates from gaged data must be used for the ungaged locations. Traditionally, empirical equations have been calibrated by regressing estimated peak discharges, which have been obtained from a log-Pearson Type-III analysis of gaged data, on watershed and precipitation characteristics. Although this method is sensitive to both extreme events and small sample sizes, problems, a particular form of the three-parameter log-normal distribution has been developed by utilizing a variate transform of the annual peak-flow series for fitting to a histogram. This mixed-mode fitting uses nonlinear least squares to optimize on the class errors between the observed and computed histograms of the data. A fixed probability range is used to control the sample variability. The mixed-mode estimator technique and the traditional technique were each used to derive parameters for 132 goage sites in Pennsylvania. Peak discharges of five different exceedance probabilities were then computed for each station and regionalized for use at ungaged sites. Regression techniques were used to relate the peak discharges to watershed and precipitation characteristics; drainage area was the only predictor variable that was necessary for accurate estimates. The average error for the mixed-mode log-normal method did not differ significantly from the log-Pearson Type-III regionalization equation error, although the range of the correlation coefficients was slightly smaller for the mixed-mode method. THE PROPERTIES OF THE KERNELS OF THE VOLTERRA SERIES DESCRIBING FLOW DEVIATIONS FROM A STEADY STATE IN AN OPEN CHANNEL,
Polish Academy of Sciences, Warsaw. Inst. of Geophysics.
J. J. Napiorkowski, and W. G. Strupczewski.
Journal of Hydrology, Vol 52, No 3/4, p 185-198, July, 1981. 5 Fig, 10 Ref.

Descriptors: *Flow characteristics, *Mathematical models, *Open channels, Channel flow, Mathematical equations, Unsteady flow.

The modeling of the deviations of the flow from the steady state in an open channel by the Volterra series is discussed. A non-linear state equation is used to derive analytically the kernels of the Volterra series. The results of the modeling presented in this paper demonstrate the effect of the type of input signal on the accuracy of approximmation of the nonlinear state equation that describes the flow deviations from a steady state by means of the integral Volterra series. The simulation of the inflow deviations from a steady state was carried out for a channel with the length five times longer than the characteristic reach. The Runge-Kutta method was used to solve the complete nonlinear set of differential equations numerically. The standard IBM procedure, in which the step of integration is chosen automatically for an imposed computational accuracy was used. Inflows of the form of rectangular pulses with different duration andd amplitude were taken as input signals. The linear and quadratic approximation for the analyzed inflows were determined. It is suggested that determination of the structure of the kernels in such a way that the convergence can be examined may be a decisive factor in further application of the Volterra series to modelling and identification of hydrological systems. VELOCITY DISTRIBUTIONS UNDER FLOATING COVERS,
Canada Center for Inland Waters, Burlington (Ontario).
Y. L. Lau.
Canadian Journal of Civil Engineering, Vol 9, No 1, p 76-83, 1982. 7 Fig, 1 Tab, 8 Ref.

Descriptors: *Velocity distribution, *Floating ice, *Streamflow, Velocity, Ice, Mathematical equations, Stream gages, Ice cover, Model studies, Turbulence.

The turbulence model was used to calculate the velocity distributions for a large number of stream flows under a variety of conditions. The results are used to review the stream gaging procedure and to examine some of the flow properties that are important in the development of many of the equations for ice-covered flow. The computed velocity distributions show that the velocity profiles are logarithmic only for about 60% of the layer thickness. For the 40% of the flow near the location of maximum velocity, the velocities are less than those given by the logarithmic distribution. The velocities at 0.2 and 0.8 of the depth may deviate significantly from the overall average velocity. However, the differences seem to compensate for each other, and the average of these two velocities is only about 2% higher than the actual mean velocity for most of the flows considered. When the depth is small and the velocity has to be measured at mid-depth, the correction needed to obtain the mean velocity can be 5% larger or smaller than the value of 0.88 generally used. The distance to the point of maximum velocity or the thickness of the rougher layer increases as the difference in the roughness of the boundaries increases. For fully rough flow, this thickness is almost independent of the relative roughness. However, when one boundary is smooth or when the flow near the boundary is not fully rough, both the Reynolds number and relative roughness can have an appreciable effect. (Baker-FRC)

INVESTIGATIONS OF CATASTROPHIC MAXIMUM DISCHARGES OF THE ARAKS RIVER,
G. T. Trembovel'skii.
Hydrotechnical Construction, Vol 15, No 7, p 423-427, 1981. 2 Fig, 1 Tab, 4 Ref. Translated from Gidrotekhnicheskoe Stroitel'stvo, No 7, p 30-32, July, 1981.

Descriptors: *Flood frequency, *Peak discharge, *Historic floods, Araks River, Euphrates River, USSR, Flood discharge, Streamflow, Rivers, Discharge frequency, Statistical analysis, Flood recurrence interval.

Historical discharge data for the Araks River, USSR, were analyzed. During 1912-1968 maximum discharges at the Karadonly basin outlet were 240-1700 cu m per sec. The May 7, 1969, flood discharge was 2700 cu m per sec., classed as catastrophic and of quite rare frequency. Data indicated that the 1969 discharge was not exceeded at least since 1888. Prior to that date floods occurred in 1868, 1850, and 1828, for which only descriptions are available. However, it is believed that these floods also did not exceed the 1969 event. Considering the synchronism of the Araks with the Euphrates, it may be assumed that a high flood occurred on the Araks in 1174. The Khudaferin bridge on the Araks, constructed in the 12-13th centuries, has a discharge capacity of 3140 cu m per sec. Distribution curves of maximum discharge were prepared by several different statistical methods and for four reference stations on the river. The best estimates of distribution parameters were obtained by the maximum likelihood method. Maximum discharges calculated by the method of moments with the 91-year series, and by Monte Carlo, Humbel, and graphico-analytical methods using the 53 and 60 year series were underestimated. The effects of the Volga River spring flood on living organisms in the North Caspian Sea were studied from 1956 to 1973. Benthic biomass was significantly correlated with flood characteristics such as volume of discharge for the flood period, date in April of the beginning of the flood, duration of rise of flood waters, duration of flooding, and rate of rise of the flood. The highest benthic biomasses (>80 g per sq m) occurred with spring floods of 120-140 cu km beginning in early April, with 75-80 days of flood water rise at a rate of 2-3 cm per day or less and a total flood duration of 100-110 days. Low benthic biomasses (30 g per sq m) were found with low flood volumes (66 cu km) beginning in May, with a rapid rise (9-10 cm per day) of short duration (30-35 days). It is important that these relationships be used as a whole, and not selectively, in optimizing water releases into the lower Volga River. (Cassar-FRC)

J. H. Krishna.
Journal of Hydrology, Vol 55, No 1/4, p 43-51, 1982. 2 Fig, 3 Tab, 8 Ref.

Descriptors: *Agricultural watersheds, *Surface runoff, *Land management, Rainfall-runoff relations, Parametric hydrology, Runoff, Model studies, Cropland, Semiarid lands, Vertisols, Hydrologic budget, Soil water, Evapotranspiration, Texas, India(Hyderabad).

A parametric water balance model (RUNMOD) was developed from hydrologic data collected from small semiarid tropical agricultural watersheds with Vertisols. Watersheds were located in Hyderabad, India, and in Texas. Individual storm runoff volumes were satisfactorily predicted, especially when good data were used for the high intensity, short duration storms. The model was also used to predict evapotranspiration and soil moisture. The model operates with limited input and helps in evaluation of the effects of different land management practices on rainfall utilization for crop production. (Cassar-FRC)

BEND THEORY OF RIVER MEANDERS. PART 2, NONLINEAR DEFORMATION OF FINITE-AMPLITUDE BENDS,
Minnesota Univ., Minneapolis, St. Anthony Falls Hydraulic Lab.
G. Parker, K. Sawai, and S. Ikeda.
Journal of Fluid Mechanics, Vl 115, p 303-314, 1982. 6 Fig, 5 Ref.

Descriptors: *Meanders, *Rivers, Mathematical studies, *Mathematical equations, *River mechanics, Statistical analysis, Alluvial channels, River beds, Channel accretion, Channel erosion, Equations.

In this paper a generalized nonlinear equation of bend migration is treated, based on a analysis in an earlier paper. An expansion technique reminiscent of the Stokes expansion for water waves is developed to perform a nonlinear stability analysis. This analysis provides an explanation of skewing and fattening, and also indicates that lateral and downstream migration rates should increase as bend amplitude develops. The analysis predicts the following nonlinear effects on bend development: reduction in lateral and downstream migration rates

below the values predicted by the linear theory; the development of positive fattening and skewing; and an increase in characteristic meander wavelength for the case of alluvial meanders. (Baker-FRC)

THREE-STATE MARKOV MODEL FOR DIFFERENTIAL PERSISTENCE,
Technical Univ. of Istanbul (Turkey). Dept. of Civil Engineering.
M. Bayazit.
Journal of Hydrology, Vol 55, No 1/4, p 339-346, 1982. 2 Fig, 7 Ref.

Descriptors: *Streamflow forecasting, *Markov processes, Rivers, Low flow, High flow, Model studies, Mathematical models.

Annual flows of some rivers exhibit differential persistence in that low flows are more persistent than high flows. A mathematical model for such flows is described, which is a three-state Markov model. States of the Markov process are defined as low, normal and high flows with respect to a lower and an upper truncation level. In the simulation of annual streamflows using this model a sequence of flow states is generated to start with, and then actual flow values are produced by means of a Markov model. This model preserves mean, variance, covariance, positive and negative run-lengths of observed flows. Charts are given to determine the values of the autocorrelation coefficient of the model. The proposed model is applied to the simulation of annual flows of a river exhibiting differential persistence, and it is found that it can satisfactorily represent the process. (Author's abstract)

TIME AND FREQUENCY DOMAIN ANALYSES OF HYDROLOGICAL SYSTEMS,
Federal Inst. of Hydrology, Coblenz (Germany F.R.).
G. Huthmann, and K. Wilke.
Journal of Hydrology, Vol 55, No 1/4, p 347-369, 1982. 10 Fig, 2 Tab, 20 Ref.

Descriptors: *Input-output analysis, *Streamflow forecasting, *Hydrologic models, *Discharge hydrographs, Rivers, *Rhine River, Nahe River, Tributaries, Forecasting, Simulation analysis, Model studies, Mathematical models, Multichannel filtering method, *Multiple frequency response analysis.

Two recently developed multiple input-single output (MISO) models were compared in an analysis of high flows of a 47.9 km Rhine River reach where discharge behavior is affected by a tributary, the Nahe River. The Wiener multichannel filtering method, used in the time domain, and multiple frequency response analysis, used in the frequency domain, were analyzed mathematically in detail. Discharge records of high flow events from 1957 to 1966 on the Rhine were used as input. Forecasting was done for the period February 4-25, 1966, and compared with observed data. There were no statistically significant differences between results from both methods. There was good agreement with recorded observations. (Cassar-FRC)

MULTI-DECISION ANALYSIS FOR LARGE-SCALE RIVER-BASIN RESERVOIR SYSTEMS,
Little (Arthur D.), Inc., Cambridge, MA.
M. Bonazountas, and J. M. Camboulives.
Journal of Hydrology, Vl 51, No 1-4, p 139-149, May, 1981. 5 Fig, 11 Ref.

Descriptors: *River basin development, *Reservoir design, Mathematical studies, *Optimization, *Optimum development plans, Reservoir operation, Flood control, Water quality control.

In order to achieve the potential benefits of river basin management, it is necessary to construct a variety of reservoirs or other secondary facilities, which must be planned and operated according to several optimization rules, and to specify a variety of objectives. Although there have been many studies of flood control, there are no examples of research on flood and water quality control for large-scale reservoir systems where the adaptive predictor for the reservoir releases is strongly influenced by that of the subsystems. A method is proposed for optimizing problems of conjunctive operation of large-scale multipurpose reservoir systems. The problem specifies three different objectives for the immediate operation of the entire system. As a result, the analysis must include formulation of an on-line optimization problem for as long as the flood lasts, of a long-term optimization problem, and of a flood-water quality problem and a search for the overall optimal policy for the entire system. Discrete dynamic programming and linear and mixed integer programming are used in the model. The overall hierarchical optimization is formulated by using the goal-coordinating method and a numerical iterative solution with two levels. Application of this method to the specified problem demonstrates the feasibility of using decomposition techniques in the search for overall optima regarding flood and water quality river control for large-scale reservoir systems. However, the solvability of the problem will depend largely on the solvability of the decomposed models and on the capability to identify saddle point conditions for the decomposed optimization. FLOOD OF APRIL 12-13, 1979 IN TUSCALOOSA AND NORTHPORT, ALABAMA,
Geological Survey, Tuscaloosa, AL. Water Resources Div.
J. R. Harkins.
Geological Survey Open-File Report 81-1057 (WRI), 1980. 1 Sheet, 15 Fig, 2 Tab, 3 Ref.

Descriptors: *Floods, *Storms, *Runoff, *Flood damage, Rainfall intensity, Streams, Flood peak, High water mark, Flood frequency, Flood recurrence interval, Historic flood, Flood plains, Flood hydrographs, *Alabama, Tuscaloosa, Northport, Black Warrior River.

The April 12-13, 1979, storm produced record flooding on the Black Warrior River at Tuscaloosa and Northport, Ala. The peak discharge exceeded the 100-year flood at the U.S. Geological Survey gaging station at Northport. Small streams in the urban areas had floods of approximately 10-year recurrence intervals. Rainfall of 9.0 inches for 24 hours ending 8:00 a.m. April 13 was equivalent to the 100-year rainfall-frequency intensity for Tuscaloosa. Flood peak elevations caused by the April 12-13, 1979, storm were determined from high water marks along streams in Tuscaloosa and Northport. These peaks are compared to historic peaks at gaging stations. The flood peak discharge on the Black Warrior River at Northport exceeded the maximum known flood of April 1900. However, the flood peak of the April 13, 1979, flow was of a lower elevation because of changes in the flood plain. (USGS)

RIVER PLUME STUDIES IN DISTORTED FROUDE MODELS,
Norwegian Hydrodynamical Labs., Trondheim. River and Harbour Lab. Div.
T. A. McClimans, and S. Saegrov.
Journal of Hydraulic Research, Vol 20, No 1, p 15-27, 1982. 4 Fig, 1 Tab, 18 Ref.

Descriptors: *River flow, *Plumes, Mathematical studies, Mixing, Destratification, Salinity, Mathematical models, Model studies, Froude number, Fjords, Orkla River, Surface tension, Simulation, Laboratory studies, Hydraulic models.

A laboratory study was performed of a river discharge to a stratified receiving basin to control a conjecture that mixing occurs predominantly in a frontal region in the absence of wind and tidal currents. Buoyant surface discharges with a densimetric Froude number of about 1 and various aspect ratios were studies in a simulated fjord basin with a seaward narrows. The results demonstrated that river plume entrainment can be simulated accurately in distorted Froude models so long as the aspect ratio of width to depth is greater than 10 in the laboratory, provided that the depth was greater than 1 centimeter for salinity stratification and greater than 4 centimeters for thermal stratification. These present results fill in some of the details regarding Haggstrom's work and extend the physics to a stratified receiving body. The hypothesis of frontal mixing was supported by the findings. A DERIVATION OF THE EQUATIONS FOR TRANSPORT OF LIQUID AND HEAT IN THREE DIMENSIONS IN A FRACTURED POROUS MEDIUM,
Cold Regions Research and Engineering Lab., Hanover, NH.
K. O'Neill, and G. F. Pinder.
Advances in Water Resources, Vol 4, No 4, p 150-164, December, 1981. 2 Fig, 65 Ref.

Descriptors: *Geothermal studies, *Porous media, *Heat transfer, Mass transfer, Heat flow, Equations, Model studies, Fracture permeability, *Groundwater movement, Groundwater flow, Pore water.

Equations are derived for the transient, three-dimensional transport of heat and mass in compressible, liquid saturated, fractured porous media. Single component thermochemical transport equations are applied to each point in the microscopic medium and are transformed to produce analogous equations in terms of variables which pertain to the scale of observation. Chemical reactions and species transport are ignored. The equations are reduced to a set of coupled, non-linear partial differential equations, which can be solved by numerical methods. The primary purpose of this study was to develop a model for simulating naturally fractured geothermal reservoirs, particularly hydrothermal reservoirs under exploitation. The equations may also be applied to underground heat storage problems, process analysis, species transport, and waste disposal problems. (Cassar-FRC)

GROUNDWATER RESOURCES OF THE WILLIAMSPORT REGION, LYCOMING COUNTY, PENNSYLVANIA,
Geological Survey, Harrisburg, PA. Water Resources Div.
O. B. Lloyd, Jr., and L. D. Carswell.
Available from State Book Store P.O. Box 1365, Harrisburg, PA 17125. Pennsylvania Geological Survey, Fourth Series, Water Resource Report 51, 1981. 69 p, 5 Fig, 2 Plates, 14 Tab, 13 Ref.

Descriptors: *Groundwater, Aquifers, *Aquifer characteristics, *Wells, Well data, Water yield, Groundwater movement, Water properties, Geohydrology, Water quality, Chemical analysis, Groundwater availability, Maps, *Pennsylvania, *Lycoming County, Williamsport region.

The aquifers that form the groundwater reservoir in the Williamsport region are composed of consolidated fractured rocks and overlying unconsolidated deposits. The fractured rocks consist of carbonate rocks, shale, siltstone, and sandstone that range in age from Ordovician to Pennsylvania. The unconsolidated deposits are Quarternary in age. The average yield of wells located and constructed for high yield is about 300 gallons per minute from unconsolidated deposits, 200 gallons per minute from carbonate rocks, 150 gallons per minute from sandstone, 100 gallons per minute from shale, and 75 gallons per minute from siltstone. The maximum yields that have been obtained range from 2.5 to 10 times these amounts. Typically, water from the carbonate rocks has a pH of 7.0, is very hard (200 milligrams per liter), and has about 450 milligrams per liter dissolved solids. Water from the noncarbonate rocks generally has a pH of 6.9, is moderately hard (85 milligrams per liter), and has about 150 milligrams per liter dissolved solids. Concentrations in excess of the Environmental Protection Agency standards for iron, manganese, sulfate, chloride, dissolved solids, hydrogen sulfide, barium, cadmium, lead, nitrate, and zinc are found locally. Available from State Book Store, P. O. Box 1365, Harrisburg, PA 17125. Pennsylvania Geological Survey, Fourth Series, Water Resource Report 50, 1981. 94 p, 14 Fig, 3 Plates, 14 Tab, 51 Ref, Append.

Descriptors: *Groundwater, Aquifers, *Aquifer characteristics, Wells, Well data, Geohydrology, Water use, Water demand, Specific yield, Transmissivity, Hydrologic budget, Water quality, Chemical analysis, Water analysis, Trace elements, Contamination, *Pennsylvania, *Cumberland County, Cumberland Valley.

Demands on water resources of the northern part of the cumberland valley have increased 70 percent in the 15 years since 1960. Total use in 1975 was about 25 million gallons per day. Data from 650 wells, 30 springs, 106 chemical and 50 coliform-bacteria analyses indicate the intensely deformed rocks can provide abundant good quality water. The median, sustained yields in gallons per minute, calculated from specific capacity data of the carbonate rocks are Tomstown, 1000; Waynesboro, 170; Elbrook, 220; Zullinger, 82; Shadygrove, 26; Stonehenge, 57; Rockdale Run, 400; St. Paul, 82; Chambersburg, 11; and in shale of the Martinsburg formation, 28. In preferred locations such as valleys or on fracture trace, wells in the carbonate aquifer may produce 2000 gallons per minute, Colluvium on the flank of South Mountain provides extra storage for the carbonate aquifer, reduces ground-water level fluctuations, lowers flood peaks, and increases flow in the Yellow Breeches Creek during drought. Joints, faults, solution enlarged openings and variations in lithology control the occurrence and movement of water. A north-south diabase dike acta as a subsurface dam. Losses from the Yellow Breeches to the Conodoguinet basin average 9000 gallons per minute. The water is hard. Moderate levels of nitrate occur in the carbonate aquifer. Iron and hydrogen sulfide are common in the Martinsburg. Flooding of subsurface structures and increasing chemical and bacterial contamination are the major problems. (USGS)

GROUNDWATER RESOURCES OF THE GETTYSBURG AND HAMMER CREEK FORMATIONS, SOUTHEASTERN PENNSYLVANIA,
Geological Survey, Harrisburg, PA. Water Resources Div.
C. R. Wood.
Available from State Book Store, P. O. Box 1365, Harrisburg, PA 17125. Pennsylvania Geological Survey, Fourth Series, Water Resources Report 49, 1980. 87 p, 4 fig, 2 Plates, 17 tab, 62 Ref.

Descriptors: *Groundwater, Aquifers, *Aquifer characteristics, *Wells, Well data, Springs, Water level, Water yield, Groundwater availability, Water use, Groundwater recharge, Pumping, Drawdown, Groundwater movement, Geohydrology, Water quality, Water pollution, Water analysis, Maps, *Pennsylvania, *Gettysburg Formation, *Hammer Creek formation.

The area of investigation is in southeastern Pennsylvania and is underlain by sandstone, shale, and conglomerate of the Gettysburg and Hammer Creek formations and by diabase dikes and sills. In 1976, about 6 million gallons per day of water was obtained from wells and springs for all uses except domestic and stock, but possibly as much as 144 million gallons per day could be pumped from the entire area. Ground water in the study area is chiefly of the calcium bicarbonate type, and its chemical quality is generally good. Most ground water occurs in and moves through very narrow bedding planes and joints. These openings, which close with depth, are developed only in a few thin beds. Median yields of nondomestic wells are 110, 85, and 6 gallons per minute in the Hammer Creek Formation, Gettysburg Formation, and diabase, respectively. Median specific capacities of nondomestic wells are 1.2, 1.0, and 0.07 gallons per minute per foot of drawdown for these same units. Nondomestic wells show little uniform relationship between specific capacity and topographic position, suggesting that water-yielding zones are no more abundant or permeable beneath valleys than beneath other topographic settings. SINKHOLE DEVELOPMENT RESULTING FROM GROUND-WATER WITHDRAWAL IN THE TAMPA AREA, FLORIDA,
Geological Survey, Tallahassee, FL. Water Resources Div.
W. C. Sinclair.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-185141, Price codes: A03 in paper copy, A01 in microfiche. Geological Survey Water-Resources Investigations 81-50, 1982. 19 p, 6 Fig, 1 Tab, 11 Ref.

Descriptors: *Sinks, *Karst, Aquifer characteristics, *Wells, Pumping, Groundwater level, Carbonate rocks, Limestone, Subsidence, *Florida, *Tampa, Floridan aquifer, Sinkholes, *Drawdown.

The area of municipal well fields on the Gulf Coastal Plain north of tampa, Fla., is densely pitted with natural sinkholes and sinkhole lakes that have resulted from collapse of surficial sand and clay into solution cavities in the underlying carbonate rocks of the Floridan aquifer. Although solution of the underlying rocks is the ultimate cause of sinkholes, some have been induced by abrupt changes in ground-water levels caused by pumping. Declines in water levels cause loss of support to the bedrock roofs over cavities and to surficial material overlying openings in the top of bedrock. The volume of calcium, magnesium, and carbonate (the constituents of limestone and dolomite) in solution in the water withdrawn from four well fields near Tampa totaled about 240,000 cubic feet in 1978. Most induced solution takes place at the limestone surface however, and the area of induced recharge is so extensive that the effect of induced limestone solution on sinkhole development is negligible. Alinement of established sinkholes along joint patterns in the bedrock suggests that a well along these lineations might have direct hydraulic connection with a zone of incipient sinkholes. Therefore, pumping of large-capacity wells along such lineations would increase the probability of sinkhole development. Although sinkholes generally form abruptly in the study area, local changes such as vegetative stress, ponding of rainfall, misalinement of structures, and turbidity in well water are all indications that percollapse subsidence may be taking place. GROUND-WATER HYDROLOGY OF JEFFERSON COUNTY, WEST VIRGINIA,
Geological Survey, Morgantown, WV. Water Resources Div.
W. A. Hobba, Jr.
West Virginia Geological and Economic Survey Environmental Geology Bulletin EGB-16, 1981. 21 p 11 Ref.

Descriptors: *Groundwater, *Water quality, Planning, *Water use, Data collections, Urbanization, Water supply, Aquifer characteristics, Pollution abatement, Groundwater availability, Wells, Springs, Sampling, Water level fluctuations, *West Virginia, *Jefferson County.

Jefferson County is an area of 211 square miles in the Valley and Ridge Physiographic Province in the eastern panhandle of West Virginia. In 1970 the population was 21,280, up 14 percent from 1960; the population for the entire State of West Virginia for the same period decreased by 6.2 percent. Many of the new housing developments are not within municipalities; therefore, individual water supplies have been developed and septic-tank systems installed. Because much of the county is underlain by fractured and cavernous limestone aquifers that are susceptible to contamination, sewage-disposal and water-supply systems are designed for minimum contamination potential. This report contains information about the occurrence, quality, and quantity of ground water in the county, and the direction of its movement. Water levels were measured at 196 well sites, and samples were collected at 188 well and spring sites. All but a few measurements and samples were collected during September 16-27, 1974. Fifteen wells and three springs were sampled for bacteria and nitrate; several of these were resampled in March and May 1975. To trace the movement of ground water, dye was injected into two sinkholes, and possible discharge points were monitored using activated charcoal to trap the dye. However, no dye was recovered, even though discharge points were monitored for as long as 8 weeks after injection. Fracture traces and faults were mapped from aerial photographs, satellite imagery, and available geologic maps. (USGS)

POSSIBILITY OF SUBSTANTIATING THE GROUNDWATER FLOW EQUATION ON THE BASIS OF THERMODYNAMICS OF IRREVERSIVBLE PROCESSES,
Akademiya Nauk SSSR, Moscow. Inst. Vodnykh Problem.
N. A. Ogil'vi.
Water Resources, Vol 8, No 2, p 136-147, March-April, 1981. 1 Tab, 13 Ref. Translated from Vodnye Resursy, No 2, p 77-89, March-April, 1981.

Descriptors: *Geothermal studies, *Gravity flow, Thermodynamics, *Groundwater movement, Mathematical equations.

A refined groundwater flow equation is derived. The interrelated processes of transport of mass, energy and heat in rocks are very complex, and therefore certain simplifications are used in modeling. When using the phenomenological description of groundwater flow processes it was assumed that rocks not containing gas or oil are completely saturated with water, that the attached (pellicular and hygroscopic) water cannot form flows, and that the relative content of attached water is very small. Lorentz and Coriolis forces and flows of elastic energy related to seismic phenomena are ignored. Under these conditions the transport phenomena are governed by the mass fluxes and heat flux for the soil skeleton, pure water, and substances dissolved in water. For groundwater with a constant composition the flow equation is analogous to the empirical Darcy equation. The refined equation allows estimating the effect of the earth's gravity field and the effect of the geothermal field on groundwater flow. (Cassar-FRC)

ASSESSMENT OF A REGIONAL AQUIFER IN CENTRAL ILLINOIS,
Illinois State Water Survey Div., Champaign; and Illinois State Geological Survey Div., Champaign.
C. B. Burris, W. J. Morse, and T. G. Naymik.
Cooperative Groundwater Report 6, 1981. 79 p 28 Fig, 5 Tab, 32 Ref, 3 Append.

Descriptors: *Aquifers, Sand aquifers, Surface water, *Pumpage, Water table decline, Reservoirs, Groundwater storage, Water level, Water supply development, *Water table fluctuations, *Groundwater recharge, Hydrologic models, Selective withdrawal, Well screens, Water table wells, *Aquifer characteristics, *Central Illinois, Groundwater availability.

This study of a major Central Illinois aquifer was initiated to determine its adequacy for both present and future needs. The objectives were to identify the geologic and hydrologic characteristics of the aquifer, and to develop a numerical model that would predict the aquifer's response to future pumpage. The aquifer's northern and southern segments are considered two separate hydrologic entities and serve nine municipalities and one industry. From 1888 to the present, withdrawals have been increasing, particularly in the north near Taylorville. In the mid-50s, and in 1976, there were serious water shortages, but conservation, completion of Lake Taylorville and development of other supplies helped restore water levels. Though supplies have increased, total water withdrawn has not risen proportionately. The average daily pumpage outside Taylorville is about 1/3 the total water withdrawn from the aquifer's northern half. As of 1980, there has been no discernable water level decline due to pumpage outside of Taylorville. The model results indicate that the aquifer can meet present and future needs of the user communities, with the exception of Taylorville, which will be at critical levels by the year 2000. Updating and expanding the surface water treatment plant at Taylorville may be a solution. Data for the south part of the aquifer show no depletion due to pumpage. By 2000, pumpage should increase from the present 270,000 gpd to 278,000, and if recharge remains the same no declines are predicted. The most critical elements of water supply development in the aquifer's south half are well design and maintenance. Well performance monitoring can detect deterioration and allow remedial actions to be taken (Atkins-Omniplan)

Seismicity in the vicinity of the Nurek reservoir in the Soviet Union has been studied. The spatial distribution of seismicity was evaluated using borehole data and data from a high-resolution seismograph network installed at Nurek in 1975. Results indicate that seismicity is not homogeneously distributed. Two distinct areas were identified. In the aseismic area vertical fluid flow is blocked by a syncline that cups the base of the reservoir. Because the strata are essentially impermeable in this area, diffusion of water to depth is restricted, and effective stress ceases to be significant. In the seismic area, a plunging anticline that crops out beneath the reservoir allows water to flow to depth along bedding planes. This structure may serve as a means of predicting the local distribution of seismicity. (titus-FRC)

QUALITY OF GROUND WATER IN ROUTT COUNTY, NORTHWESTERN COLORADO,
Geological Survey, Lakewood, CO. Water Resources Div.
K. J. Covay, and R. L. Tobin.
Geological Survey Water Resources Investigations Open-File Report 80-956, 1981. 38 p, 8 Fig, 1 Plate, 6 Tab, 17 Ref.

Descriptors: *Groundwater, *Water quality, *Aquifers, *Geohydrology, Aquifer characteristics, Water yield, Wells, Springs, Water use, Water demand, Water analysis, Chemical analysis, Bacteria, Water quality standards, Maps, *Colorado, *Routt County, Yampa River basin.

Chemical and bacteriological data were collected to describe the quality of water from selected geologic units in Routt County, Colo. Calcium bicarbonate was the dominant water-chemistry type; magnesium, sodium, and sulfate frequently occurred as codominant ions. Specific conductance values ranged from 50 to 6,000 micromhos. Mean values of specific conductance, dissolved solids, and hardness from the sampled aquifers were generally greatest in waters from the older sedimentary rocks of the Lance Formation, Lewis Shale, Mesaverde Group, and Mancos Shale, and least in the ground waters from the alluvial deposits, Browns Park Formation, and the basement complex. Correlations of specific conductance with dissolved solids and specific conductance with hardness were found within specified concentration ranges. On the basis of water-quality analyses, water from the alluvial desposits, Browns Park Formation, and the basement complex generally is the most suitable for domestic uses. Chemical constituents in water from wells or springs exceeded State and Federal standards for public-water supplies or State criteria for agricultural uses were pH, arsenic, boron, chloride, iron, fluoride, manganese, nitrite plus nitrate, selenium, sulfate, or dissolved solids. Total-coliform bacteria were detected in water from 29 sites and fecal-coliform bacteria were detected in water from 6 of the 29 sites. (USGS)

STREAM-AQUIFER INFLUENCE COEFFICIENTS AS TOOLS FOR SIMULATION AND MANAGEMENT,
Colorado State Univ., Fort Collins. Engineering Research Center.
T. Illangasekare, and H. J. Morel-Seytoux.
Water Resources Research, Vol 18, No 1, p 168-176, February, 1982. 6 Fig, 42 Ref.

Descriptors: *Aquifers, *Streamflow forecasting, *Water management, Streams, Pumping, Model studies, Water table, Drawdown, Wells, *Surface-groundwater relations.

The discrete kernel approach for an isolated aquifer is combined with the discrete kernel approach for an isolated stream to derive influence coefficients for a combined stream-aquifer system. The influence coefficients establish explicit relationships between the controllable decision variables and known initial conditions and the resulting states of the combined system. The aquifer and stream systems are coupled using a linear relation for the aquifer-stream interaction. A hypothetical system is used as an example. The effects of pumping from one or two wells in an aquifer adjoining a river are determined on the aquifer level, the direction of flow between river and aquifer, and the river level in three river reaches. LIBRARY U. OF I., URBANA-CHAMPAIGN

Techniques for combining or coupling regional groundwater flow models are evaluated. The two principal techniques described are linking and embedding. In the use of linking, the economic model and the hydrologic model are run at different stages: the economic model is run with known hydrologic factors (e.g., drawdown); the hydrologic model is then run with the output of the economic model as demands and the cycle are repeated. In the case of bedding, two approaches are used: difference equations and response functions. Using difference equations, the groundwater hydrogeology is molded by a set of linear equations derived from the partial differential equations of flow through porous media, and this set of equations is embedded directly into the eonomic model as a constraint set. Using response functions, a linear relationship between drawdown and stress (e.g., pumping) can be determined. It was found that the linking technique is preferrable for highly non-linear hydrologic systems, and that the response function approach is preferred for linear flow systems (and non-linear flow systems where good linear approximations exist or where a transformation can induce a linear system). NUMERICAL SIMULATION OF A THICK FRESHWATER LENS: PEARL HARBOR GROUNDWATER MODEL,
Hawaii Univ. at Manoa, Honolulu. Water Resources Research Center.
C. K. Clark, L. S. Lau, and J. F. Mink.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-243296, Price codes: A05 in paper copy, A01 in microfiche. Technical Report No 139, December, 1981. 71 p, 14 Fig, 2 Tab, 31 Ref, 2 Append. OWRT A-090-HI(1), 14-34-0001-1113.

Descriptors: *Aquifer characteristics, *Computer models, *Groundwater movement, *Hydrologic models, Hydrogeology, Mathematical models, Numberical analysis, Darcy's law, *Hawaii, Simulation analysis, dispersion, Ghyben-Herzberg lens, Pearl Harbor aquifer.

The freshwater aquifer in the Pearl Harbor area on Oahu, Hawaii is the most important water resource of the island and constitutes a large proportion of its freshwater supply. The aquifer has a freshwater lens up to 304.8 m (1000 ft) thick floating on top of a saline water zone. Mechanisms of groundwater movement are extremely complex because the upper boundary is confined near the coast and phreatic inland, while the lower boundary is nowhere confined. In this study, regional groundwater movement due to various pumping schemes is mathematically simulated by a set of partial differential equations. These equations are then solved numerically with a finite difference approximation. The location of the freshwater and saltwater interface, which constitutes the lower boundary of the system model was estimated by Hubbert's formula. Consideration was also given to features concerning geohydrologic boundaries of the Pearl Harbor aquifer. It was concluded that a mathematical model can be used as a tool in the management of groundwater development in a thick Bhyben-Hergzerg aquifer. Improvement of system simulation may be achieved by adding a mass transport element to study hydrodynamic dispersion within a transition zone where fluid density changes gradually. (Author abstract)

TRACING INTERAQUIFER CONNECTIONS IN THE KEFAR URIYYA-AGUR REGION (ISRAEL), USING NATURAL URANIUM ISOTOPES,
TAHAL--Water Planning for Israel, Ltd., Tel Aviv (Israel).
J. Guttman, and J. Kronfeld.
Journal of Hydrology, Vol 55, No 1/4, p 145-150, 1982. 4 Fig, 1 Tab, 6 Ref.

Descriptors: *Uranium radioisotopes, *Aquifers, *Saline water, *Isotope studies, Radioisotopes, Senonian aquifer, Cenomanian aquifer, Groundwater movement, Kefar Uriyya-Agur, *Israel, Tracers.

The natural uranium isotopic technique was used to detect a hydrologic connection between two strata in the Kefar Uriyya-Agur region west of Jerusalem, Israel. The Senonian aquifer, which overlies the Cenomanian aquifer, contains low-grade uranium phosphates. The natural U content of water samples from the aquifers were: Senonian, 60 micrograms per liter; Cenomanian under Senonian, 1-50 micrograms per liter; and Cenomanian not overlain by Senonian, 1-2 micrograms per liter. A relationship between the thickness of the overlying Senonian and the excess U234 activity was also demonstrated. This evidence shows that the Senonian aquifer is connected to, and contributes to, the water of the Cenomanian aquifer. This may account for the transfer of salinity, indigenous in the very poor quality Senonian aquifer, to the important Cenomanian aquifer. (Cassar-FRC)

EVIDENCE FOR A SHALLOW HIGHLY-PERMEABLE ZONE IN THE CHALK OF HAMPSHIRE, U.K.,
Southern Water Authority (England).
H. G. Headworth, T. Keating, and M. J. Packman.
Journal of Hydrology, Vol 55, No 1/4, p 93-112, 1982. 12 Fig, 3 Tab, 24 Ref.

Descriptors: *Aquifers, *Geologic fissures, *Permeability, Streamflow, Groundwater, *Chalk aquifer, Candover River, Transmissivity, Storativity, Water level fluctuations, Pumping tests, Carbonate aquifers, Flow augmentation, Rivers, United Kingdom, *England(Hampshire).

The Chalk Aquifer in England is most productive 20-50 m below the water table. Yield from this very fine grained limestone formation decreases with depth. Most of the active storage and permeability is confined to fissures making up 1-2% of the total volume. However, river abstraction studies in the Candover catchment in Hampshire revealed the existence of an unusually well-fissured 6 m thick zone. In the Candover catchment annual groundwater fluctuations are only 3-5 m (one-third of those in other areas), the water table is unusually flat (1 in 500 gradient), and storativity is 5-7% (compared with 1-3% elsewhere). Studies of streamflows during and after long-term pumping tests suggested that the fissured zone acted as an important conduit to streamflows. Streamflows entering the river in its upper and lower reaches are similar, suggesting that the river is fed by different levels of the aquifer having similar response times (transmissivity/storativity ratios). The upper and lower aquifer zones appear to be hydraulically connected and controlled by the same head. Extensive pumping from the aquifer into the river produced a concentration of depression which decreased streamflows for several months after pumping had stopped. (Cassar-FRC)

AN ENRICHED FINITE ELEMENT FOR SIMULATION OF GROUNDWATER FLOW TO A WELL OR DRAIN,
Wright State Univ., Dayton, OH. Dept. of Geology.
T. M. Tharp.
Journal of Hydrology, Vol 55, No 1/4, p 237-245, 1982. 5 Fig, 11 Ref.

Descriptors: *Finite element method, *Wells, *Drains, Fluid flow, Simulation analysis, Groundwater movement, Porous media, Model studies.

A quadrilateral finite element was developed to simulate a well or drain in two-dimensional fluid flow through porous media. The enriched four-node element models the logarithmic head distribution about a well located at its center. The enriched element is compatible at its broundaries with unenriched elements and can represent head boundary conditions at the well. The element is most accurate with a large ratio of element diameter/well diameter and for coarse meshes, as are used in regional groundwater studies. Accuracy is less for dense arrays with very large ratios of well diameter/element diameter. (Cassar-FRC)

Water Resources Bulletin, Vol 18, No 2, p 325-330, April, 1982. 2 Fig, 6 Tab, 13 Ref.

Descriptors: *Aquifer characteristics, *Regression analysis, *Transmissivity, Graphical analysis, Storativity, Pumping tets, Drawdown, Wells, Artesian aquifers, Confined aquifers, Leaky aquifers, Water table aquifers.

A method for determining aquifer transmissivity and storativity, which avoids the errors inherent in graphical analysis, is described. Regression analysis of the nonsteady time drawdown field data is performed by hand held calculator. Examples are given for four situations: a well penetrating a confined aquifer, a production well fully penetrating a nonleaky artesian aquifer, a leaky artesian aquifer, and a water table aquifer. Comparison of results showed that this method is a viable alternative to Theis or Jacob graphical solutions for nonleaky artesian aquifers. However, it did not perform well for leaky artesian aquifers at small values of time or for water table aquifers. (Cassar-FRC)

CAPE COD AQUIFER, CAPE COD, MASSACHUSETTS,
Geological Survey, Providence, RI.
B. J. Ryan.
Journal of the New England Water Works Association, Vol 96, No 1, p 25-54, 1982. 8 Fig, 5 Tab, 49 Ref.

Descriptors: *Aquifers, *Water supply, *Geohydrology, Cape Cod, *Massachusetts, Groundwater, Water quality, Hydrologic properties, Recharge, Groundwater recharge, Groundwater pollution, Saline water intrusion, Wells, Municipal water, Saline-freshwater interface, Water pollution sources, Wastewater disposal, Salt, Deicers, Recreation.

Existing information on the Cape Cod Aquifer, Massachusetts, was compiled. As of 1978 over 100 municipal wells and 15,000 private wells were withdrawing water from the aquifer, which is composed of unconsolidated deposits of sand, gravel, silt, and clay. Bedrock ranges from 80 to 900 ft below sea level. The aquifer is unconfined except

along the north shore between Bourne and Brewster, along the south shore, and at Chatham and Orleans. There is a saline-freshwater mixing zone where chloride concentrations range from 25 to 18,000 mg per liter. Natural recharge (average 18 inches per year) is from precipitation infiltrating into the sandy soils. Discharge is from wells, evapotranspiration, evaporation from the water table and seepage to rivers, marshes, and ocean. Water quality is generally good low in dissolved solids, soft, and mildly acidic. Dominant ions are Na and Cl. In some locations water is naturally high in Fe, Mn, hydrogen sulfide, and salt. Contamination has resulted from land-deposited wastewaters, solid waste disposal dumps, deicing salt storage areas, spills of chemicals and fuels, urban runoff, and saline-water intrusion. In 1978 6.4 billion gallons were pumped by public water systems for supplying 80% of the population, which in 1975 ranged from 127,000 in winter to 382,000 in summer. Alternative drinking water sources are desalination of saline water, transport from the mainland, and rainwater cisterns. (Cassar-FRC)

GROUND-WATER RECONNAISSANCE OF PART OF THE LOWER KENAI PENINSULA, ALASKA,
Geological Survey, Anchorage, AK. Water Resources Div.
G. L. Nelson, and P. R. Johnson.
Geological Survey Open-File Report 81-905 (WRI), 1981. 32 p, 16 Fig, 10 Ref.

Descriptors: *Groundwater, *Glacial aquifers, *Aquifer characteristics, *Geohydrology, Wells, Natural recharge, Water yield, Well logs, Surface-groundwater relations, Glacial drift, Glacial sediments, Groundwater potential, *Alaska, Kenai Peninsula Borough, Ninilchik, Anchor Point.

Most residential and industrial development of the Lower Kenai Peninsula, Alaska, is along the coast of Cook Inlet. Most of the information about subsurface conditions is obtained from wells along the coast. Ground water is recharged by local precipitation, and slow drainage of ground water to the streams maintains streamflow during winters and periods of no precipitation. Sedimentary bedrock of the Tertiary Kenai Group is the principal source of water to wells, but subsurface data are too sparse to differentiate individual aquifers within the bedrock. Most bedrock wells are completed in poorly consolidated sandstone. Glacial till overlies bedrock in much of the study area, but few wells obtain water from the poorly permeable till. Glacial outwash and abandoned-channel deposits in major drainageways of alluvial plains provide water to wells but are little utilized and have not been explored by drilling. Intermorainal valleys and areas of low relief are poorly drained, and bog deposits overlie surficial materials in parts of the area. Bog deposits contain highly colored, iron-rich water that is undesirable to most consumers. Lacustrine clays overlie and are interbedded with fluvial materials and contain little extractable water. Streams have incised older glacial sediments and deposited alluvium along the present flood plains. Where the alluvium is thick enough, it has good potential for providing ground water to high-capacity wells. However, production of ground water from alluvium or other deposits hydraulically connected to streams will reduce streamflow. Surficial deposits with the best potential for developing significant ground-water supplies in the study area are the deltaic complex near the mouth of Kasilof River, the alluvium of Crooked Creek, and abandoned-channel deposits in the alluvial plain near Ninilchik and in an ancestral drainageway of Tustumena Glacier south of Crooked Creek. COMPUTER SIMULATION OF THE STEADY-STATE FLOW SYSTEM OF THE TERTIARY LIMESTONE (FLORIDAN) AQUIFER SYSTEM IN EAST-CENTRAL FLORIDA,
Geological Survey, Tallahassee, FL. Water Resources Div.
C. H. Tibbals.
Geological Survey Open-File Report 81-681 (WRI), 1981. 31 p, 10 Fig, 4 Tab, 20 Ref.

Descriptors: *Groundwater, *Simulation analysis, *Confined aquifers, *Groundwater movement, Limestone, Recharge, Springs, Transmissivity, Computer models, *Florida, East-central Florida, Floridan aquifer.

The predevelopment steady-state ground-water flow system for 13,700 square miles of the Tertiary limestone aquifer system (known as the Florida aquifer in Florida) in east-central Florida is simulated by means of a digital computer model. The model results indicate that about 1,900 cubic feet per second recharges the aquifer as downward leakage from the surficial aquifer. The average recharge rate where recharge actually occurs (approximately 6,550 square miles) is about 4 inches per year. The maximum recharge rate is about 14 inches per year. An additional 21 cubic feet per second is recharged to the modeled area of the aquifer by means of lateral boundary inflow along the northeast boundary. The Floridan aquifer system, as simulated, discharges 1,300 cubic feet per second as springflow, 540 cubic feet per second as diffuse upward leakage to the surficial aquifer in an area of approximately 7,150 square miles and 81 cubic feet per second as lateral boundary outflow to the southwest and to the east. The average transmissivity of the upper unit of the aquifer, as simulated, is about 120,000 square feet per day while that for the lower unit is about 60,000 square feet per day. (USGS)

HYDROLOGY AND THE EFFECTS OF INDUSTRIAL PUMPING IN THE NIKISKI AREA, ALASKA,
Geological Survey, Anchorage, AK. Water Resources Div.
G. L. Nelson.
Geological Survey Open-File Report 81-685 (WRI), 1981. 22 p, 11 Fig, 5 Ref.

Descriptors: *Groundwater, *Water use, *Industrial water, *Pumping, *Drawdown, Recharge, Aquifer systems, Water level fluctuations, Lakes, Water quality, Saline water intrusion, Groundwater potential, *Alaska, Nikiski.

Industries in the Nikiski area pumped about 4.2 million gallons of water per day from three aquifers in 1979. The upper confined aquifer, from which most of the water is pumped, is recharged by leakage from the overlying unconfined aquifer. The unconfined aquifer is hydraulically connected to lakes and streams. The lower confined aquifer, the deepest of the three aquifers, is hydraulically poorly connected to the other two aquifers. Drawdown caused by pumping appears to have stablized in all three aquifers, but water levels continue to fluctuate in response to annual changes in precipitation. In the lower two aquifers, the potentiometric surfaces near some production wells are below sea level; however, no salt water had intruded the aquifers as far as the pumped wells. If additional water supplies are needed, another potential site for ground-water development is the Beaver Creek basin, 7-10 miles east of the industrial area. (USGS)

2G. Water In Soils

EFFECTS OF USE PATTERN, COVER, SOIL DRAINAGE CLASS, AND OVERWINTER CHANGES ON RAIN INFILTRATION ON CAMPSITES,
Ohio Agricultural Research and Development Center, Wooster.
J. P. Vimmerstedt, F. G. Scoles, J. H. Brown, and M. C. Schmittgen.
Journal of Environmental Quality, Vol 11, No 1, p 25-28, January-March, 1982. 5 Tab, 22 Ref.

Descriptors: *Rainfall, *Infiltration, Rainfall infiltration, Soil types, Infiltration rate, Sedimentation, Erosion, Rainfall-runoff relationships, Sediment yield, Simulation, Storms, Land use, Recreation, *Campsites, Vegetation effects, *Seasonal variation, *Drainage patterns.

Objectives of this study were to determine the effect of soil drainage class, vegetative cover, and intensity of use within a campsite on rainfall infiltration, sediment yield, and soil bulk density. The changes occurring in various parameters over the winter season were also determined. Campsite conditions at 15 Ohio Public campgrounds were used as the study sites. Infiltration and sediment yield were measured during 60 minute applications of 11 cm of simulated rain on campsite use zones, using a spray infiltrometer. Initial percentages of infiltration were 82 and 89 in fall and spring with sod cover, and 68 and 79 in fall and spring with hardwood cover. Initial infiltration also varied with use zone and season: heavy use showed 52% in the fall, 65% in the spring; moderate use showed 79% in the fall, and 87% in the spring; and light use showed 95% in fall and 99% in spring. Fall infiltration during the last 10 min of simulated streams on poorly drained soils was 4% with sod cover vs 12% with hardwood cover. On well drained soils, the cover effect was reversed. Final infiltration rate and total infiltration changed but little from one use zone to another on poorly drained campsites, but on well- or excessively drained soils there was a marked and progressive reduction in infiltration from light to moderate and heavy use zones. Sediment concentration in runoff and soil bulk density increased with use intensity. (Baker-FRC)

THE EFFECT OF RAINDROP IMPACT ON THE DYNAMICS OF SOIL SURFACE CRUSTING AND WATER MOVEMENT IN THE PROFILE,
Israel Soil Conservation and Drainage Div., Emek Hefer. Soil Erosion Research Station.
J. Morin, Y. Benyamini, and A. Michaeli.
Journal of Hydrology, Vol 52, No 3/4, p 321-335, July, 1981. 10 Fig, 3 Tab, 13 Ref.

Descriptors: *Rainfall infiltration, *Infiltration rate, *Surface sealing, Soil profiles, Loess, Sand, Permeability coefficient, Clays, Mathematical studies, *Soil types, Mathematical models.

The infiltration of rainfall into bare soil was studied in field and laboratory experiments on two types of soil in Israel: hamra, a soil composed of 85 percent sand and 13 percent clay, and loess. The formation of a crust with an hydraulic conductivity several orders of magnitude lower than that of the soil profile was the primary process governing

LIBRARY U. OF I., URBANA-CHAMPAIGN

the infiltration rate. The decrease in hydraulic conductivity is attributed to the organization of a very thin layer on the soil surface. The sealing efficiency of this crust is achieved by suction forces which arrange soil particles, probably clay, into a continuous, dense layer. Conditions of unsaturated flow in the soil profile below the crust result from the decrease in flux through the crust. An analytical model was used to analyze the dynamics of the changes in the different soil parameters from the beginning of the rainfall until the soil crust was completely formed. (Carroll-FRC)

USE OF SPECTRAL DATA TO ESTIMATE THE RELATIONSHIP BETWEEN SOIL MOISTURE TENSIONS AND THEIR CORRESPONDING REFLECTANCES,
Purdue Univ. Lafayette, IN. Water Resources Research Center.
J. B. Peterson, and M. F. Baumgardner.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224528, Price codes: A03 in paper copy, A01 in microfiche. Technical Report No 143, 1981, 36 p, 22 Fig, 19 Ref, 4 Append. OWRT A-061-IND(2).

Descriptors: *Soil water, *Soil moisture, *Remote sensing, *Reflectance, Moisture tension, Optical properties, Soil properties, Soil types.

Fifty-seven soils covering a wide range were studied for the relationship between their loss in reflectance when wet versus their oven dry reflectance. Regression analysis revealed R2 values of .196 and .963 for the water absorption bands and of .845 for one of the visible bands, 0.52 to 0.58 um. Twelve of the soils were brought to equilibrium with 1/3 and 1/10 bar moisture levels and compared with oven dry. This study revealed that soils of high cation exchange capacity generally exhibited very low reflectance when moist whereas a stairstepped relationship existed for the sandier soils. To further appraise the effect of different moisture levels to reflectance, 11 soils were equilibrated at 10 and 15 bar moisture tension and the spectral data compared with those for oven dry, 1/3 and 1/10 bar. Reflectance data for oven dry, 15, 10, 1/3 and 1/10 on these samples revealed three general patterns of spectral response for these soils. The fine textured soils showed low reflectance for the wetter levels with little differentiation; the sandy soils showed much higher, brighter responses for the drier samples than for the wetter moisture levels. A more even gradient of reflectance existed for the silt loams. However, there were enough exceptions to these groupings to indicate the presence of other causative factors than color and/or texture not yet evaluated.

ESTIMATION OF MOISTURE EXCHANGE OF GROUNDWATER WITH ROCKS OF THE ZONE OF AERATION IN THE WINTER AND SPRING,
A. A. Konoplyantsev, V. K. Sedova, and I. V. Obukhova.
Water Resources, Vol 8, No 2, p 148-154, March-April, 1981. 5 Fig, 2 Tab, 9 Ref. Translated from Vodyne Resursy, No 2, p 90-97, March-April, 1981.

Descriptors: *Groundwater level, *Aeration zone, *Freezing, Thawing, Soil water, Infiltration, Frozen ground, Precipitation, Seasonal variation, Water storage.

Observations of the moisture content and temperature of the rocks of the zone of aeration, the level and temperature of the groundwater, and meteorological factors were studied under natural conditions from 1968 to 1979 in an experimental area near Moscow. The confined aquifer occurred in unequigranular fluvioglacial sands of permeability 0.5 to 30 m per day. Groundwater level was 3.5-4.5 m. In winter and spring moisture was discharged from the groundwater level to the zone of aeration. The amount of moisture discharged varied from 2.5 to 55.4 mm. The quantity of moisture drawn from the groundwater level during freezing depended on the moisture storage in the rocks of the zone of aeration at the start of freezing. The smaller the zone of aeration, the larger were the quantities of moisture drawn from the groundwater level. When the moisture content of the rocks in the zone of aeration was less than 12%, the rock moisture content was directly related to the rate of freezing of the ground and little or no moisture was withdrawn from the groundwater level in winter. In spring the groundwater level rose, starting in March or early April. This rise was caused by the inflow of moisture stored in the zone of aeration, not from infiltration of precipitation. Only after complete thawing of rocks in the zone of aeration did infiltration of precipitation begin. Thawing of rocks began at lower depths and proceeded toward the surface. As thawing progressed, the moisture content of the rocks increased, and the groundwater level began to rise long before thawing was completed. (Cassar-FRC)

AN APPROXIMATE METHOD OF ESTIMATING SOIL WATER DIFFUSIVITY FOR DIFFERENT SOIL BULK DENSITIES,
Centro de Energia Nuclear na Agricultura, Sao Paulo (Brazil).
P. L. Libardi, K. Reichardt, C. Jose, and M. Bazza.
Water Resources Research, Vol 18, No 1, p 177-181, February, 1982. 5 Fig, 2 Tab, 15 Ref.

Descriptors: *Diffusivity, *Soil density, *Infiltration, Density, *Soil water, Bulk density, *Estimating equation.

Reichardt and Libardi's method (1973) for determining the effect of soil bulk density on soil water diffusivity and infiltration was extended to 13 soils varying in density from 0.900 to 1.7 g per cu cm. Dry soils were placed in 50 cm long plastic cylinders and tapped to produce several bulk density values for each soil. A generalized equation was presented to express the soil water diffusivity for any soil as a function of the soil water content and soil bulk density, knowing the rate at which the wetting from advances for one value of bulk density. OPTIMIZATION PRINCIPLE FOR AIR AND WATER MOVEMENT,
Griffith Univ., Nathan (Australia). School of Australian Environmental Studies.
J-Y. Parlange, R. D. Braddock, R. W. Simpson, and D. E. Hill.
Soil Science, Vol 133, No 1, p 4-9, January, 1982. 1 Fig, 1 Tab, 12 Ref.

Descriptors: *Earth-water interfaces, *Mathematical equations, Optimization, *Soil water, Leaching, Sediment transport, Solute transport, Air-water interfaces, Groundwater movement, Subsurface water.

The aim of this paper is to describe the structure of the water profile and accurately predict water intake using an optimization principle. The principle can be used first of all to accurately predict water intake into a soil when air movement is not negligible. The principle is also useful for solving the transport equation numerically, avoiding numerous iterations. Finally, analytical approximations can be greatly improved when the principle is taken into account. These three applications of the optimization principle are illustrated by comparisons with an exact solution of the water movement equation obtained using Brutsaert's technique. (Baker-FRC)

REDUCED RUNOFF AND NONPOINT SOURCE POLLUTION THROUGH INCREASED INFILTRATION,
Pennsylvania State Univ., University Park.
A. R. Jarrett, and J. R. Hoover.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224759, Price codes: A07 in paper copy, A01 in microfiche. Report, November 1981. 114 p, 34 Fig, 9 Tab, 58 Ref. OWRT A-055-PA(1), 14-34-0001-1140.

Descriptors: *Surface runoff, *Nonpoint pollution sources, *Rainfall infiltration, *Infiltration capacity, *Soil water, Runoff, Rainfall-runoff relationships, Infiltration, Infiltration rate, Free water, Air entrainment, Sand, Intestitial water, Soil porosity, Pervious soils, Soil tests, Soil saturation, Agricultural runoff, Agricultural hydrology, Technology.

Three studies were carried out to assess the effects of increased soil infiltration on the reduction of runoff and nonpoint source pollution. The first study examined surface venting of entrapped soil air for increasing infiltration in sand. Simulated rainfall was applied to a large 75 cm thick sand sample having 13 different surface variations or venting mechanisms, with soil-air pressure measured at seven piezometer locations and runoff recorded. Air entrapment reduced water infiltration, while the installation of air wells, holes, and vertical mulch columns significantly increased infiltration rates. The second study estimated the kinetic energy of escaped soil air and its effect on the detachment of soil particles in dry and saturated soil conditions. Also examined was the combined effects of overland flow, escaped soil air, and its transport by overland flow. In the third study, a preliminary field study showed that shallow drainage systems reduced air entrapment, peak runoff, total runoff, sediment concentration and sediment load on tilled land. Where air entrapment is a problem, farmers can install subsurface drain tiles to enhance infiltration and soil water storage capacity. (Zielinski-MAXIMA)

ON DETERMINING VOLUMETRIC SOIL MOISTURE VARIATIONS IN PEAT BY THE GRAVIMETRIC METHOD,
Toronto Univ. (Ontario). Dept. of Geography.
D. S. Munro.
Soil Science, Vol 133, No 2, p 103-110, February, 1982. 3 Fig, 2 Tab, 17 Ref.

Descriptors: *Soil water, *Porosity, *Saturated soils, Peat, Beverly Swamp, Hamilton, Ontario, Volumetric analysis, Organic matter, Soil porosity, Soil density, Density.

The most suitable method for determining soil moisture during a three-summer weekly sampling program of periodically flooded peat was the volume ration method. This method determined the ratio of water in the sample to total sample volume. It was sensitive only to error in sampling the water fraction of the soil. The effect of the error was small in porosity estimates made from unsaturated peat samples and would probably be even less important in estimating the soil moisture fraction of unsaturated soil. Volume ratio estimates of soil porosity in Beverly Swamp, near Hamilton, Ontario, were: samples above the water table, 0.821 in the surface layer, decreasing to 0.642 at 50-60 cm depth; and samples below the water table, 0.863 in the surface layer, decreasing to 0.750 at 60-70 cm depth. The more common method of measuring soil mositure by multiplying in situ bulk density by sample weight ratio of water to solid

produced unreasonable results, 0.82-0.86 throughout the soil profile. Standard errors in the volume method (0.003-0.039) were less than standard errors in the weight method (0.03-0.05). (Cassar-FRC)

SOIL WATER AVAILABILITY,
Science and Education Administration, Temple, TX. Grassland, Soil and Water Research.
J. T. Ritchie.
Plant and Soil, Vol 58, No 1-3, p 327-338, 1981. 4 Fig, 1 Tab, 12 Ref.

Descriptors: *Available water, *Soil water, *Evapotranspiration, *Root zone, *Soil-water-plant relationships, *Model studies, Transpiration, Soil water potential, Mathematical studies, Drainage, Subsurface drainage, Evaporation, Hydrologic budget.

The upper and lower limits of soil water availability are often difficult to define because of water flow into and out of the root zone and because of incomplete extraction by sparse roots at the lower boundaries of the root zone. For accurate soil water balance modelling, it is important to obtain accurate measurements of these upper and lower limits in the field. A simple field-measured drainage function is described for determining the time when water is available above the upper limit while soils are draining. The extractable water may then be estimated using only soil water content measurements taken preferably by a neutron meter. Once the range of extractable soil water is established, some general relationships to reduce transpiration can be established. Above 70% of the range of extractable soil water, transpiration is affected little by soil water deficit. In dry regions where evapotranspiration is the critical factor in soil water balance modelling, accurate calculations of transpiration are vital. (Geiger-FRC)

A FIELD METHOD FOR MEASURING SHORT-CIRCUITING IN CLAY SOILS,
Soil Survey Inst., Wageningen (Netherlands). Dept. of Soil Physics.
J. Bouma, L. W. Dekker, and C. J. Muilwijk.
Journal of Hydrology, Vol 52, No 3/4, p 347-354, July, 1981. 4 Fig, 7 Ref.

Descriptors: *Clays, *Soil moisture retentiion, Soil physics, *Soil types, Vertical flow, Flow characteristics, *Soil water, Flow measurement, *Unsaturated flow, Field tests.

Vertical flow of free water along the walls of macropores in unsaturated soils, a process called short-circuiting, has been observed in clay soils in the field during natural rainfall and during sprinkling irrigation. A method for measurement of short-circuiting in the field is described. A cylinder with a diameter and height of 20 centimeters is filled with undisturbed surface soil and is placed on a perforated disk in a funnel. The funnel is supported to allow periodic measurement of the volume of outflow from the soil. This assembly, together with a similar assembly with no surface soil, is placed along the track of a spray gun used for sprinkling irrigation. At least four samples can be measured during one run, while the assembly without soil measures the total water applied to the soil. The measured short-circuiting in a heavy clay soil, in a light clay soil with two different types of structure in and adjacent to potato ridges, and in a heavy clay soil with two types of surface microrelief is reported. Results of these measurements show that the tortuosity of the macropores and their size distribution significantly affect the degree and duration of short-circuiting. Increasing the microrelief of heavy clay soil was found to significantly retard sort-circuiting. Reduction of short-circuiting is advisable, since this phenomenon results in the rapid movement of irrigation water to the subsoil without benefit to the roots of plants and without wetting and leaching the soil between macropores. In addition, short-circuiting may result in rapid movement of surface-applied fertilizers to deeper layers. (Carroll-FRC)

THE RELATIONSHIP BETWEEN 018 AND DEUTERIUM IN WATER IN SAND COLUMNS UNDERGOING EVAPORATION,
Commonwealth Scientific and Industrial Research Organization, Glen Osmond (Australia). Div. of Soils.
G. B. Allison.
Journal of Hydrology, Vol 55, No 1/4, p 163-169, 1982. 2 Fig, 1 Tab, 12 Ref.

Descriptors: *Isotope studies, *Evaporation, *Deuterium, *Oxygen isotopes, Recharge, Groundwater recharge, Arid lands, Water vapor, Stable isotopes, Groundwater.

Slopes produced by plotting deuterium against 018 (% relative to standard mean ocean water) were as follows: soil water in unsaturated sand subjected to evaporation in columns for 3.8 to 15.8 days, 2.4 to 4.6; water evaporating from an open pan, 5. The lower slope values corresponded with the longer evaporation times in the columns. This effect is produced by the increasing thickness of sand through which the water must travel. In the beginning of the evaporation period water movement to the surface is predominantly by liquid flow, and the slopes are similar to the saturated case. As evaporation proceeds and the water must travel further to reach the surface, the vapor phase movement predominates and the 018-D relationship changes. The suggests that in very arid areas groundwaters replenished by local recharge are characterized by lower 018-D slopes. (Cassar-FRC)

LEACHING FRACTIONS AND SALT STATUS OF TWO IRRIGATED GYPSUM-RICH SOILS IN SOUTHERN ALBERTA,
Department of Agriculture, Lethbridge (Alberta). Research Station.
C. Chang, S. Dubetz, T. G. Sommerfeldt, and D. C. MacKay.
Canadian Journal of Soil Science, Vol 62, No 1, p 97-103, February, 1982. 2 Fig, 3 Tab, 14 Ref.

Descriptors: *Soil chemistry, *Irrigation, Leaching, Soil water, Salinity, Salts, Calcium, Mathematical studies, *Alberta, *Canada.

The objectives of this study were to determine the changes in soil salinity at two field sites and to develop a new method for calculating the leaching fractions in typical irrigated soils near Tilley, Alberta, after more than 60 years of flood irrigation. This information is useful in assessing the adequacy of existing irrigation practices. Two sites with long term salinity status records were selected. The salt content in the surface 60 cm of soil was initially lower than that below, and remained fairly low throughout the years of irrigation. The rate of leaching of salts below 60 cm was very fast in the beginningd decreased to 1.6% of the initial rate at Tilley 1. The salt content in the soil apparently reached a pseudosteady state after 43 yr of irrigation. About 7 years were required for one pore volume of water to leach through the 180 cm profile. After 7 years of irrigation about half of the leachable salt was leached out of the soil profile. Since the average calcium content of the soil profile decreased linearly with time, the crop uptake of calcium was small compared to the total annual losses of calcium. The main loss of calcium was attributed to leaching. Drainage volume was obtained from the use of calcium concentration in the saturated extracts of soil rich in gypsum and the net leaching loss of soluble calcium. The results of this study indicate that the new method developed by determining drainage volume is reliable. The water balance method is simple, but it requires accurate data on the annual rate of irrigation and precipitation, and on crop consumptive use. (Baker-FRC)

Descriptors: *Reservoirs, *Nutrients, *Adsorption, *Phytoplankton, Reservoir stages, Phosphates, Nitrates, Ammonium, Silica, Diatoms, Algal growth, Bottom sediments, Clay.

The development of phytoplankton and some chemical aspects of the water composition were studied over a two-year period following the filling of a new reservoir. The bottom of the reservoir is lined with clay material of high ion exchange capacity. The total adsorptive capacity of this material, including the clays with chemically bound aluminum and iron, decreased the nutrient content of the reservoir water by adsorption of cations and anions. Dissolved silica in particular was adsorbed. As a result, silica became a limiting factor for diatom growth during the first year of observation. Samples of the bottom material were collected from various sites in the reservoir and their adsorption capacity tested by incubating with seawater samples for 24 hr in the laboratory. These studies showed that 28 mg Si/sq m were fixed in 24 hr. Some of the orthophosphate and ammonia in the water was also adsorbed in laboratory experiments; in field studies, no clear distinction between abiogenic and biogenic factors could be made with respect to phosphate and ammonia removal. During the first year of the investigation sufficient phosphate and ammonia were still present to permit phytoplankton growth. Biological removal of phosphate predominated. Nitrates were not adsorbed. Calcium. Magnesium and chlorides also decreased due to the effects of the reservoir bottom: nevertheless this decrease was insignificant. (Carroll-FRC)

ALGAL BIOASSAY OF THE PORTAGE LAKES, SUMMIT COUNTY, OHIO,
Akron Univ., OH. Dept. of Biology.
J. H. Olive, and G. Higgins.
Environmental Pollution, Series A, Vol 26, No 1, p 59-67, 1981. 3 Fig, 3 Tab, 22 Ref.

Descriptors: *Algal, *Bioassay, *Lakes, Nutrients, Phosphates, Nitrates, Lentic environment, Lotic environment, *Ohio, Summit Ccounty, *Portage Lakes.

The Portage Lakes are a series of natural lakes and man-made reservoirs in the upper Tuscarawas River of northeastern Ohio. Algal bioassays were used to determine the effects of phosphate and nitrate enrichment on the algal growth potential in the lakes and to predict the effects of diverting algal nutrients from one part of the lake ystem to another area within the system. The temporal patterns of water fertility appeared to be different for standing waters than for those with more of the characteristics of running waters, probably as a result of differences in nutrient availability. In lentic environments, algal growth rates ranged from about 0.6 doublings per day in early summer to less than 0.2 doublings per day in late summer. Algal growth rates in more lotic environments increased from between 0.2 and 0.3 doublings per day in June to between 0.3 and 0.5 doublings in July, followed by a decline to less than 0.3 doublings per day in August. Nutrient enrichments with PO4-P and NO3-N suggested that phosphorus was usually the major limiting nutrient in both groups of lakes, although NO3-N additions sometimes stimulated algal growth in the lotic environments. PRIMARY PRODUCTION IN SALINE LAKES,
Saskatchewan Univ., Saskatoon. Dept. of Biology.
U. T. Hammer.
Hydrobiologia, Vol 81, p 47-57, 1981. 3 Fig, 2 Tab, 28 Ref.

Descriptors: *Saline lakes, *Primary productivity , Lakes, *Phytoplankton, Plankton, Reviews, Variability.

The paper compares the results of several studies made on the variability of primary production in saline waters and related parameters. Phytoplankton primary production is discussed in terms of hourly volumetric rates, daily volumetric rates, areal rates, annual rates of primary production, chlorophyll a and a photosynthetic capacity, and efficiency of integral photosynthesis. Also presented are factors which influence algal biomass and rates of primary production. Photosynthetic bacterial primary production, macrophyte primary production, and Aufwuchs primary production are also reviewed. While extensive work has been done in establishing upper limits of photosynthesis in saline lakes, major problems still exist regarding the usefulness of light and dark bottles for accurately measuring the rates in highly productive lakes. Also, the factors which limit production in saline lakes should be examined more closely along with further studies into aquatic macrophytes and Aufwuchs production. (Baker-FRC)

A COMPARISON OF VASCULAR VEGETATION AND PROTOZOAN COMMUNITIES IN SOME FRESHWATER WETLAND OF NORTHERN LOWER MICHIGAN,
Virginia Polytechnic Inst. and State Univ., Blacksburg. Center for Environmental Studies.
M. S. Henebry, J. Cairns, C. R. Schwintzer, and W. H. Yongue.
Hydrobiologia, Vol 83, No 3, p 353-375, 1981. 2 Fig, 13 Tab, 80 Ref.

Descriptors: *Wetlands, *Protozoa, Marshes, Bogs, Fens, Swamps, Eutrophication, Chemical properties, Aquatic animals, *Ecosystems, Lakes, Vegetation, *Michigan.

This study was designed to examine vegetation, water levels, water chemistry and Protozoa in the major wetland types to determine similarities and differences among wetland types and extent of covariation between vegetation, Protozoa, and water characteristics. The wetlands included in the study were located in Emmet and Cheboygan counties in northern lower Michigan. The bedrock consists of dolomites and limestone, but outcrops are rare and most of the surface is covered by glacial deposits. Seven wetlands were sampled in the summer of 1977. Two were bog sites and were vegetated by tree, tall-shrub, and ground layers. The vegetation in the remaining sites consisted entirely of a ground layer. Two marshes studied did not have a dominant species. In the Hebron Swamp, duckweed was the leading dominant with leatherleaf and cattail condominant. Early to midsummer water levels were well below the surface in the bogs, slightly below the surface at the fens where water was observed at the soil surface at some sample points, and well above the surface in the two marshes and Hebron swamp. The wetlands examined formed three distinct groups with respect to vascular vegetation and midsummer water levels. They formed two distinct groups with respect to chemistry of the standing waters. The similarities and differences between wetland sites were not as great for Protozoa as for vascular vegetation, but the patterns were similar. The open waters at the fed and bog sites and at the Cheboygan marsh may have been highly eutrophic. It was concluded that the structure and dynamics of protozoan communities of wetlands seem to be broadly different from that of other freshwaters, and somewhat unique to particular wetland types. Descriptors: *Saline lakes, *Limnology, *Pyramid Lake, Lakes, *Nevada, Lake stages, Lake morphology.

This paper seeks to update earlier reports on Pyramid Lake and to compare this lake with other athalassic saline lakes and synthesize past studies into a more holistic treatment. Pyramid Lake occupies a large, north-south oriented graben wholly within the boundaries of the Pyramid Lake Paiute Indian Reservation in northwestern Nevada. The eastern shore is abruptly determined by the Lake Range's fault scarp, while the western shore is bounded by the Virginia Range. The headwaters of the Truckee River, the only permanent water source, arise in the Sierra Nevada mountains of eastern California and western Nevada. Although classified as saline, this lake does not fill all the characteristics of that classification. About the only characteristic that the Pyramid Lake shares with all athalassic saline lakes is its lack of outflow. The allochthonous contributions from the Truckee River figure significantly in Pyramid's dynamics. Certainly the reproductive success of the anadromous fishes depends on this river. The composition of the benthic substrate is quite homogeneous, but the shoreline development is high, unlike many other saline waters. The vertical water column provides substantial spatial heterogeneity, not noted in shallower, polymictic saline waters. The lake does not contain a well-developed macrophyte community. It is concluded that the lake does not fix large amounts of energy, providing an exception to the generalization that saline lakes are highly productive. The rich biological community of the lake is a dramatic departure from the low species diversity classically associated with inland saline waters. (Baker-FRC)

ON THE CHEMISTRY OF SOME SALT LAKES AND PONDS IN YUGOSLAVIA,
Bioloski Inst., Belgrade (Yugoslavia).
G. Petrovic.
Hydrobiologia, Vol 81, p 195-200, 1981. 7 Fig, 1 Tab, 10 Ref.

Descriptors: *Saline lakes, *Chemical properties, *Yugoslavia, Lakes, Ponds, Magnesium, Calcium, Acidity, Sulfates, Chlorides, Carbonates, *Pannonian plain.

This paper is concerned with some salt lakes and ponds occurring on the Pannonian plain in Yugoslavia. Chemical features are reported of about 75 shallow alkaline lakes and ponds in this region. Geologically the plain represents the evolution of a desiccated basin in which the role of surface and underground water has been significant. Color of the water varied from green to brown. Salinity varied from 0.376 to 13.5%. pH values were seldom below 8.0, being usually between 8.5 and 9.5. All three types of major saline water occurred: carbonate, sulfate and chloride. Sodium bicarbonate and sodium/magnesium bicarbonate waters predominate, and calcium bicarbonate waters were rare. Such chemical diversity reflected the geological nature of the region, the arid climate, the variety in the chemical nature of the soils, the small distance of saline underground water from the surface, and the occurrence of flooding by the Rivers Danube and Tisa. The data reveal that waters on the Pannonian plain outside Yugoslavia have similar ionic compositions to those inside and display a similar range of salinity. It is noted that saline waters of similar chemical composition to those recorded in Yugoslavia occur in many parts of the world. (Baker-FRC)

ALGAL BIOASSAY OF THE WATER FROM TWO LINKED BUT CONTRASTING WELSH LAKES,
University Coll. of North Wales, Bangor. School of Plant Biology.
C. M. Happey-Wood, and A. Pentecost.
Freshwater Biology, Vol 11, No 5, p 473-491, 1981. 8 Fig, 4 Tab, 49 Ref.

Descriptors: *Algal growth, *Lakes, Eutrophication, Nitrogen, Phosphorus, Nutrients, *Bioassay, *Diatoms, Seasonal variations, Thermal stratification, Wastewater, *Wales, Llyn Padarn, Llyn Peris.

Bioassay experiments were conducted for a year using the diatom to assess differences in fertility of water samples from Llyn Padarn and Llyn Peris by growth of Asterionella formosa in filtered water samples and to investigate nutrient limitation by enrichment of these filtered water samples. A rapid bioassay procedure employing C-14 labeled A. formosa was developed as a more sensitive means of assessing the differences in nutrient status of the waters of the two lakes. Water samples were collected every 2 weeks, from a depth of 3 meters. In unenriched water, growth was more rapid in Padarn water during autumn-winter-spring, but there was no significant difference between growth in water from the two lakes during the period of thermal stratification. Mean growth rates in treatments with additions of nitrogen and chelated iron were not significantly different from unenriched water samples, both between treatments and in lakes during thermal stratification. Phosphate additions increased growth in water from both lakes. The potential fertility of water samples from the two lakes differs more during mixed water conditions than in the period of thermal stratification. The addition of diluted sewage effluent which enters the drainage system between the two lakes resulted in similar rates of growth of A. formosa in water from both lakes. (Baker-FRC)

ON THE CHEMISTRY AND BIOTA OF SOME SALINE LAKES IN WESTERN AUSTRALIA,
Adelaide Univ. (Australia). Dept. of Zoology.
M. C. Geddes, P. De Decker, W. D. Williams, D. W. Morton, and M. Topping.
Hydrobiologia, Vol 82, p 201-222, 1982. 6 Fig, 5 Tab, 37 Ref.

Descriptors: *Saline lakes, *Ecosystems, Biota, Salinity, *Australia, *Chemical properties, *Limnology, Lakes, Sodium, Chlorides, Ions.

The limnology of salt lakes in Western Australia was investigated. Water bodies studied were those accessible from the highway between Kalgoorlie, Wiluna, Meekathara, Northam, Lake Grace, Esperance and Norseman, an area of some 800 by 500 km. The study was undertaken in 1978 with about 100 water bodies being sampled. Fifty-four had salinities of 3% or more, and only these are considered in this paper. Crustaceans were by far the dominant group and were represented by twenty-one species of ostracods, ten of anostracans, ten of copepods, three of cladocerans, and one of the Conchostraca and Am phipoda. The halobiont gastropod, Coxiella, was collected from 10 localities. Nematodes were noted in one. No relationship was noted between basin size and fauna. The major factors affecting distribution appeared to be salinity and geographic position. The pattern of major ion dominance was almost always sodium, magnesium, calcium, potassium, and chlorides, sulfate, and bicarbonate in order of decreasing concentrations, with sodium and chloride the dominant cation and anion respectively on all occasions. While this study presents the occurrences of similarities between the fauna of salt lakes in the southwest and southeast of Australia, it also highlights the differences. The most significant result of the studies is the addition of further evidence of greater diversity in the salt lake fauna in the west. (Baker-FRC)

THE LIMNOLOGY OF SALINE LAKES IN WESTERN VICTORIA, A REVIEW OF SOME RECENT STUDIES,
Adelaide Univ. (Australia). Dept. of Zoology.
W. D. Williams.
Hydrobiologia, Vol 82, p 233-259, 1981. 7 Fig, 5 Tab, 108 Ref.

Descriptors: *Saline lakes, *Limnology, Reviews, *Australia, Seasonal variations, Chemical properties, Acidity, Salinity, Dissolved oxygen, Sedimentation, Lake sediments.

This review considers studies of the major physical, chemical and faunistic features of saline lakes in Western Victoria, but does not consider botanical studies, estimates of primary and secondary production or palaeolimnological findings. The lakes in question lie about 150 km west-southwest of Melbourne in a region known as the Western District of Victoria. Most lakes lie at altitudes of greater than 150 miles above sea level. All are the termini of inland drainage basins, and the area is almost entirely endorheically drained. The climate is temperate, with warm dry summers and cool wet winters. The region is now almost totally used for agricultural purposes. Physical limnology (morphology, temperature, and light), chemical limnology (concentration of dissolved solids, ionic composition, sources of dissolved salts, pH, dissolved oxygen, and sediment composition), and faunal studies (relationship between salinity and occurrence, composition, evolution, adaptations, and seasonal changes) are included in the review. THERMAL REGIMES OF FLORIDA LAKES, A COMPARISON WITH BIOTIC AND CLIMATIC TRANSITIONS,
Florida Univ., Gainesville. Dept. of Environmental Engineering Sciences.
J. R. Beaver, T. L. Crisman, and J. S. Bays.
Hydrobiologia, Vol 83, No 2, p 267-273, 1981. 5 Fig, 2 Tab, 18 Ref.

Descriptors: *Lake classification, *Lakes, *Thermal properties, Hydrothermal studies, *Florida, Seasonal variation, Cycling nutrients, Climatic zones, Limnology, Mixing, Water circulation, Lake morphometry, Thermal regimes.

The extent of latitudinal variation in the thermal structure and mixing regime of warm monomictic lakes in Florida is quantified and related to major biotic and climatic zones within the state. Temperature profiles were determined monthly during 1979 for 24 lakes and bimonthly for 5 lakes in peninsular Florida. Zonal thermal differences were nearly eliminated during summer, as evidenced by the fact that August was the only month for which no significant temperature differences existed between any geographic zone, suggesting that differences in the regional thermal regimes of lakes in Florida are related principally to the extent and duration of winter temperature minima. Of 36 statistical comparisons made, only 7 cases displayed a significant temperature difference between shallow and deep lakes for a given month, and no clear trend could be discerned for any lake group. Thus, due to the generally shallow nature of Florida lakes and the less pronounced seasonal temperature fluctuations, basin morphometry does not appear to play as important a role in determining the thermal regimes of Florida lakes as seen for northern lakes. These findings support the contention that the American system for classifying lakes according to their mixing regimes is more concise than the European system but does not provide for transitional lake types. While it is not proposed that the term warm monomictic be revised to formally account for transitional lakes, it is suggested that annual patterns of nutrient cycling and algal productivity in climatically transitional areas such as peninsular Florida may be strongly influenced by intraregional differences in lakes' circulation patterns. THE DECLINE OF SALVINIA MOLESTA ON LAKE KARIBA,
Lake Kariba Fisheries Research Inst., (Zimbabwe).
B. E. Marshall, and F. J. R. Junor.
Hydrobiologia, Vol 83, No 3, p 477-484, 1981. 3 Fig, 2 Tab, 47 Ref.

Descriptors: *Lakes, *Ecosystems, Eutrophication, *Zimbabwe, *Lake Kariba, Aquatic plants, Salvinia molesta, *Nutrients, Limnology, Reservoir stages, Ferns.

Ecological aspects of Lake Kariba and their possible effects on the decline of Salvinia in Kariba are discussed. During the early post-impoundment years, Lake Kariba was eutrophic as a result of nutrients leached from flooded land, but it rapidly became less eutrophic as these nutrients were lost through the outflow. During this time an explosive growth was noted among several aquatic organisms, of which Salvinia was perhaps the most striking example. The lake reached its full supply level in July 1963, by which time many sheltered areas suitable for Salvinia disappeared and the effects of wave action on the exposed mats became more pronounced. Extensive mats are still found on the lake, but are restricted to the larger estuaries, notably those of the Gachegache, Bumi and Sibilobilo River Basins. No obvious link could be noted between the decline of Salvinia and physico-chemical conditions of the lake. Several factors acting synergistically were probably responsible, including direct attack by Paulinia as well as the indirect effects of competition for nutrients with other ecosystgem components of the developing lake. The ecological effects of the decline of Salvinia on Lake Kariba are not clear. The mats provided a substrate for fish food organisms as well as a cover for various species. Submerged macrophytes will probably fill both of these roles now. The effects on shoreline vegetation will perhaps be more significant. Nutrient retention in the lake, once carried out by the Salvinia, is now carried out more efectively by other ecosystem components. (Baker-FRC)

AN ECOLOGICAL STUDY OF AN ANTARCTIC FRESHWATER POOL WITH PARTICULAR REFERENCE TO TARDIGRADA AND ROTIFERA,
Department of Science, Melbourne (Australia).
D. A. Everitt.
Hydrobiologia, Vol 83, No 2, p 225-237, 1981. 6 Fig, 7 Tab, 54 Ref.

Descriptors: *Lakes, *Polar regions, Antarctic, Benthos, Benthic Environment, Aquatic Life, Biomass, *Rotifers, *Ecology.

This paper records the seasonal population changes of two metazoan groups, rotifers and tardigrades, in a freshwater tarn in Antarctica. Deep Lake Tarn is a small, permanent body of freshwater in the Vestfold Hills, Princess Elizabeth Land, Antarctica. The surface area is 6,200 square meters and maximum depth is 0.45 meters. It is frozen solid for 8 months of the year and is partially or completely melted during the remaining four. Most of the tarn's bottom is a soft, black, anoxic mud overlain with a luxuriant algal carpet. Water was sampled seven times for nutrient analysis from up to seven stations. The benthic algal mat was comprised of cyanophytes, chlorophytes, chrysophytes, a pyrrophyte, rotifers, tardigrades, nematodes, protozoans and bacteria. A sharp rise was noted in all animals when the tarn melted. The ability to cryptobiose or form resistant eggs and the reproductive behavior of tardigrades and rotifers may account for their particular success in the Antarctic environment. A new species of tardigrade (Isohypsibius) is reported. Light intensity ranged from zero in winter to a maximum of 0.22 Langleys/minute during December. Water temperatures ranged from zero to 12.5 degrees C. Nutrient levels were generally similar to those of the sea and other lakes in the area. Nutrients are believed to be of marine origin and transported to the tarn via the meltstream. (Baker-FRC)

HORIZONTAL DISTRIBUTION OF CHLOROPHYLL IN THE BIELERSEE (DIE HORIZONTALE VERTEILUNG VON CHLOROPHYLL IM BIELERSEE),
Bern Univ. (Switzerland). Zoologisches Inst.
J. V. Orelli.
Schweizerische Zeitschrift fur Hydrologie, Vol 43, No 1, p 168-175, 1981. 4 Fig, 2 Tab, 6 Ref. English Summary.

Descriptors: *Chlorophyll, *Primary productivity, *Lakes, Algae, Eutrophication, Population dynamics, Limnology, Mathematical studies, Sampling, Variation coefficient, *Bielersee.

One goal of current studies in the Bielersee is that of reliably estimating primary production. The morphology of the lake and the effects of the principal influents imply that samples taken at one point may not be representative. Therefore samples were collected at 0.10 m depth at 15 different points throughout the lake body and analyzed for chlorophyll content. The time-averaged chlorophyll content for the different sites varied from a value of 10.8 mg/cu m with a coefficient of variation of about 50%. No explanation was apparent for the two extremal time averages of 13.2 and 8.8 mg/cu m at two sampling sites. The variation coefficient for the mean chlorophyll contents at all the sampling sites on 14 different dates between April and October 1977 averaged 32%. A clear explanation for the time variation was apparent in the phytoplankton growth stages, which did not occur synchronously throughout the lake. However, the variation between the values at individual sampling sites on individual dates was considerable, and therefore a single value can scarcely be considered representative for the entire lake. The correlations between the 14 measurements at a given site and the values at other sites were analyzed to see whether on site could be selected as optimally representative. In general, the sites near the lake center were most representative. For a reliable representation of algal biomass and primary prductivity throughout the year, it is more suitable to perform frequent measurements at a single site than less frequent measurements at various sites. Descriptors: *Seston, *Trophic level, *Algae, Eutrophication, Lakes, Detritus, Invertebrates, Zooplankton, Phytoplankton, Cyanophyta, *Kremenchug Reservoir, *Russia, Seasonal variation, Organic matter, Bacteria.

LIBRARY U. OF I., URBANA-CHAMPAIGN

Seston in Kremenchug Reservoir varied from 2 to 5000 g per cu m dry weight during 1970-72. Seasonal variations in the water column in 1972, a year of lower eutrophication, were 2.2-14.0 g per cu m in spring, 2.4-76.0 g per cu m in summer, and 1.7-13.2 g per cu m in fall. The average seston content (in g per sq m) for the entire reservoir was 52 in May, 133.5 in July, and 35.3 in October of 1972. In July 1971 the average seston concentration in a blue-green algae bloom was 550 g per sq m. In 1972 the relative amount of organic matter in the seston varied from 18 to 52% in May, from 24 to 82% in July, and from 20 to 78% in October. Values were generally higher in the lower and deeper zones than in the upper and shallower zones, as well as in areas where blue-green algae were predominant. During the 1972 vegetative period algae comprised 1.7-82.0% of the organic part of the seston; bacteria, 0.9-74.6%; and invertebrates, 0.001-8.7%. In stretches where young algae predominated, proportions of bacteria in the organic part of the seston were 1-2%. As the algae aged, the bacteria increased to 20-40%. Comparisons with data from other lakes showed that highly eutrophic lakes had 0.04-3.6% zooplankton in the seston, and mesotrophic lakes 7-9.8%. Kremenchug Reservoir had 0.04% zooplankton in a bloom zone in 1970 (whole lake area). There was a correlation between individual components of the organic matter of the seston and between the latter as a whole and its components. (Cassar-FRC)

THE PH HISTORY OF LAKES IN SOUTHWESTERN SWEDEN AS CALCULATED FROM THE SUBSOIL DIATOM FLORA OF THE SEDIMENTS,
Umea Univ. (Sweden). Dept. of Ecological Botany.
I. Renberg, and T. Hellberg.
Ambio, Vol 11, No 1, p 30-33, 1982. 6 Fig, 30 Ref.

Descriptors: *Lakes, *Diatoms, Monitoring, Water quality, Acidity, Acid precipitation, *Sweden, *Sediments, Lake sediments, Sedimentation, *Hydrogen ion concentration, History.

The method of Hustedt's pH-system has been improved and applied in elucidating the pH history of some acidified lakes in southwest Sweden. The lakes studied included Gardsjon, Harsvatten, and Lysevatten, all situated about 10 km east and soouthest of Stenungsund in Bohuslan. The soil in the region is thin, with frequent outcrops of bedrock. The drainage basins of the lakes are forested. Lake shores shelve rather steeply in many places, and the marginal belt of macrophytic vegetation is generally sparse. The composition of the diatom spectrum in a sediment sample depends on the pH of the lake water at the time the sediment was laid down. Diatom samples from the lowermost part of the long sediment core from Gardsjon, representing the transitional zone between the mineral sediments of glacial origin and the true lake sediment, were dominated by a periphytic and relatively acidophilous flora, with many valves of Nitzschia and Fragilaria species. No marine species were found. Six to seven centimeters below the sediment surfaces there was the start of a drastic change in the diatom flora. These lakes came into existence after the deglaciation of the region about 12,500 years ago. The minerogenic sediment in the lowest samples of the long core from Gardsjon was deposited during the final stage of that period. The diatoms in these sediment samples are peryphytic species, many of which are classified as acidophilous, and which are derived both from the lake basin and from the streams and various shallow water bodies. After its formation the lake was more eutrophic than it was later on, and its pH was just below 7. Lakes in Sweden then became more and more oligotrophic and acidic. A sudden fall in pH from 6 to 4.5 during the last few decades, probably due to precipitation falling on the region, has changed the diatom flora dramatically. (Baker-FRC)

SURFACE HEAT FLUXES FROM LAKE ONTARIO: FURTHER VERIFICATION OF LAKE THERMAL MODEL,
Little (Arthur D.), Inc., Cambridge, MA.
W. A. Tucker.
Water Resources Research, Vol 18, No 1, p 77-82, February, 1982. 5 Fig, 2 Tab, 16 Ref.

Descriptors: *Heat transfer, *Evaporation, Lakes, *Lake Ontario, *Model studies, Cloud cover, Heat flow, Stratified lakes, Thermal properties.

A one-dimensional heat transfer/thermal structure model was used to estimate the components of heat flux at the surface of Lake Ontario during July-October 1972. Model inputs were lake geometry, water optical properties, and surface weather observations. Comparisons of the heat flux components with estimates obtained from observations showed that the next flux was accurately predicted by the model, but the radiative input to the lake was significantly overestimated. This error was a result of a deficiency in the expression accounting for the effect of cloud cover on insolation. Errors in sensible and latent heat fluxes were compensating, producing an accurate value for net heat flux. Evaportation rates predicted by the model were 50% higher than an average of estimates obtained using seven other methods. (Cassar-FRC)

METABOLIC ACTIVITY OF HERBIVOROUS ZOOPLANKTON IN LAKE KINNERET (ISRAEL) DURING 1972-1977,
Kinneret Limnological Lab., Tiberias (Israel).
M. Gophen.
Journal of Plankton Research, Vol 3, No 1, p 15-24, 1981. 5 Fig, 5 Tab, 19 Ref.

Descriptors: *Zooplankton, *Lakes, *Biomass, *Metabolism, *Food chains, Grazing, Water temperature, Aquatic productivity, Aquatic populations, Respiration, Aquatic animals, *Lake Kinneret, *Israel.

The metabolic activities of the herbivorous grazer zooplankton community in Lake Kinneret, Israel were studied from 1972 to 1977. For most years, two peaks for metabolic activity were found: the first in May-June and the second in October-November. Two distinct metabolic periods were found during the entire study period, namely from January 1972 to June 1974 and from June 1974 to December 1976. In 1974-1975, there was a significant increase in the sardine (Mirogrex terraesanctae-terraesanctae) population. The herbivore communities were reduced by Mirogrex during June 1974-1976. The high summer temperatures of the epilimnic water caused increased respiration rates from July through November. The late summer-early fall peak of zooplankton biomass is probably due to a slowing of Mirogrex feeding or an increase in water temperature. Seasonal cumulative food consumption, respiration, productivity, and defecation values for 1975-1977 were lower than 1972-1974 values. The highest defecation activity occurred during April-June when a high level of inedible material was present in the lake. No significant increases in relative and absolute densities of larval stages were found in 1975-1977 compared to 1972-1974. It was likely that the grazed food increased in nutritional value between 1974 and 1975. (Geiger-FRC)

NUTRIENT DISTRIBUTION IN NORTH GERMAN LAKE SEDIMENTS AND REMARKS ON SEDIMENT-PELAGIC EXCHANGE (DIE NAHRSTOFFVERTEILUNG IN SEDIMENTEN NORDDEUTSCHER SEEN UND HINWEISE AUF DEN AUSTAUSCH SEDIMENT-PELAGIAL),
Akademie der Wissenschaften der DDR, Berlin. Inst. fuer Geographie und Geookologie.
G. Mothes.
Acta Hydrochimica et Hydrobiologica, Vol 8, No 1, p 35-46, 1980. 6 Fig, 1 Tab, 10 Ref. (No English summary).

Descriptors: *Lake sediments, *Cycling nutrients, *Lakes, Limnology, *Germany, Phosphorus, Eutrophication, Productivity, Nutrients, Sediments, Chemical composition, Stagnant water.

As part of a large-scale research program on material dynamics in lakes and wetlands of North Germany (centered on Stechlin Lake), investigations were conducted on nutrient distribution and transfer in lake sediments. Sediments are closely involved in the questions of nutrient resupply for primary production, persistence of sedimented seston, and stability of water bodies relative to environmental events. Sediment samples were collected at maximum depths from lakes Stechlin, Nehmitz (north and south basins), Grosse Fuchskuhle, Dagow, Jabel (central and northern basins) and Globsow. These lakes represented oligotrophic and eutrophic, low and high productivity, and overfertilized types. Fractions of dry matter, ash mass, calcium carbonate, carbon, nitrogen, phosphorus and silica in the sediments were analyzed. The phosphorus distribution in the sediment was found to represent the most useful indicator of lake status. In addition to total phosphorus, the ratio of phosphorus in interstitial water to particulate fraction and the ratio of orthophosphate to total phosphate in the interstitial water play an essential role. An increase in C:P ratio in an eutrophicated water body occurs during restoration, with carbon oxidation in the sediment. Because of the stabilizing effect of lake sediments, lake restoratin by cleanup of inputs or supplemental aeration takes decades to become significant, while eutrophication can occur in a few years. Specific sediment conditions for the individual lakes are discussed. (Carroll-FRC)

DECOMPOSITION OF UREA BY SIZE-FRACTIONATED PLANKTONIC COMMUNITY IN A EUTROPHIC RESERVOIR IN JAPAN,
Yamagata Univ. (Japan). Dept. of Chemistry.
Y. Satoh.
Hydrobiologia, Vol 83, No 1, p 153-160, 1981. 3 Fig. 3 Tab, 34 Ref.

Descriptors: *Reservoirs, *Plankton, Phytoplankton, Lakes, Bacteria, Seasonal variations, *Urea, *Biodegradation, Microbial degradation, Kinetics.

Phytoplankton is usually considered responsible for most of the urea decomposition occurring in natural waters. Free bacteria had been found to be inactive for urea decomposition in previous studies. In the present study, free bacterial populations were separated from an intact planktonic community in water of a eutrophic reservoir in Japan by filtration through Whatman GF/C glass fiber filters (mean porosity .2 micron). Urea decomposition by the free bacterial populations and the intact planktonic community was determined in six different months. The count of free heterotrophic bacteria increased during the urea decomposition experiments, but the urea concentration did not decrease. Thus, the separated free bacteria apparently did not take part in urea decomposition. On the other hand, urea was decomposed by the intact planktonic community in five out of six cases. The phytoplankton in the sixth case was hypothesized to have been in a sensecent state. Thus it appears that phytoplankton were responsible for most of the urea decomposition. Rate constants were calculated at 0.00-0.63/day with a mean value of 0.21/day, assuming that urea decomposition obeyed first-order kinetics. (Baker-FRC)

THE MICROFAUNA OF ALGAL MATS AND ARTIFICIAL SUBSTRATES IN SOUTHERN VICTORIA LAND LAKES OF ANTARCTICA,
Virginia Polytechnic Inst. and State Univ., Blacksburg. Dept. of Biology.
D. D. Cathey, B. C. Parker, G. M. Simmons, Jr., W. H. Yongue, Jr., and M. R. Van Brunt.
Hydrobiologia, Vol 85, No 1, p 3-15, 1981. 2 Fig, 9 Tab, 28 Ref.

Descriptors: *Cold regions, *Aquatic fauna, *Species composition, *Lakes, Iced lakes, Glacial lakes, *Antarctica, *Algal mats, Benthic fauna, Southern Victoria Land, Protozoa, Rotifers, Tardigrades, Invertebrates.

This paper reports results of the first study of the microfaunal community inhabitating the littoral and benthic zones of eight Antarctic dry valley

lakes. General taxonomic compositions were given for six lakes and detailed community composition analyses for two lakes. Four major faunal groups were identified on algal mat samples and artificial polyurethane foam substrates: protozoa, rotifers, tardigrades (Hypsibus antarcticus), and nematoes (rare and not further identified). The lakes differed in limnological properties and in distribution ofmicrofauna. Protozoans were the most diverse, with 88 taxa belonging to 40 genera identified in Lakes Fryxell and Hoare in 1978-79. The most productive lake, Fryxell, had the greatest number of protozoan taxa (55). The shallow Lake Chad also had an abundant microfaunal community in comparison with the other lakes. For the first time, dinoflagellates (Gymnodinium andd Glenodinium) were identified in this region. Since all lakes had similar temperature and light regimes, the differences in faunal composition in these remote Antarctic lakes were probably caused by the variations in physical and chemical properties of the lakes. The distribution of the fauna followed patterns similar to those seen in temperature lakes. (Cassar-FRC)

DIEL VARIATIONS OF CERTAIN PHYSICO-CHEMICAL PARAMETERS OF WATER IN SELECTED AQUATIC SYSTEMS,
Agricultural Research and Education Center, Sanford, FL.
K. R. Reddy.
Hydrobiologia, Vol 85, No 3, p 201-207, 1981. 2 Fig, 1 Tab, 15 Ref.

Descriptors: *Aquatic plants, *Diel variatins, *Physicochemical properties, *Seasonal variation, Water hyacinth, Ponds, Ammonium, Nitrates, Phosphates, Bicarbonates, Carbonates, Hydrogen ion concentration, Dissolved oxygen, Eutrophic lakes, Elodea, Cattails, *Lake Apopka, *Florida, Lakes, Macrophytes, Algae, Vegetation effects, Nutrients, Water quality.

Diel variations in physical and chemical parameters were determined in waters from a drainage canal containing water hyacinth (floating plant), a water hyacinth pond, an elodea (submerged plant) pond, a cattail (emersed plant) pond, a pond without aquatic macrophytes (control), and eutrophic Lake Apopka, Florida. Parameters measured in the October, January, May, and July (1979-80) samplings were dissolved oxygen, pH, dissolved carbon dioxide, bicarbonate and carbonate alkalinity, ammonium-N, nitrate-N, phosphate-P and conductivity. Water in hyacinth ponds showed little or no diel or seasonal variation in dissolved oxygen, pH, dissolved carbon dioxide and bicarbonate alkalinity. In aquatic systems with no floating vegetation (elodea, cattail, control, and Lake Apoka) dissolved oxygen increased to a high of 5-20 micrograms per ml at midday and decreased to 2-8 micrograms per ml at night. The pH of the waters ranged from 8-9.5 during midday to 7-8 at night. In systems with no floating vegetation bicarbonate levels decreased during daylight and carbonate levels increased. An inverse relationship between carbonate and bicarbonate alkalinity was seen at night. No carbonates were detected in the water hyacinth ponds. No diel variations in N (ammonium and nitrate) or P (phosphate) were observed in any systems. (Cassar-FRC)

MINERAL COMPOSITION OF PHRAGMITES AUSTRALIS IN SCOTTISH LOCHS AS RELATED TO EUTROPHICATION. I. SEASONAL CHANGES IN ORGANS,
Dundee Univ. (Scotland). Dept. of Biological Sciences.
Y. B. Ho.
Hydrobiologia, Vol 85, No 3, p 227-237, 1981. 3 Fig, 7 Tab, 48 Ref.

Descriptors: *Seasonal variation, *Nutrients, *Eutrophication, *Lakes, Aquatic plants, Eutrophied lakes, Trophic level, Plant physiology, Reeds, *Scotland, Phragmitess australis, Forfr Loch, Balgavies Loch, Lowes Loch.

Levels of N, P, K, Na, Ca, Mg, and Fe in root, rhizome, stem, leaf, and panicle of the common reed (Phragmites australis) were determined monthly from March to November 1975 in 3 Scottish lakes: Forfar (very eutrophic), Balgavies (eutrophic), and Lowes (mesotrophic). Mineral levels in root, rhizone, and panicle showed no consistent seasonal changes. Aboveground organs, the leaf in particular, had higher levels of ash, N, K, Ca, and Mg than the belowground parts; the reverse was true for Na and Fe. The concentrations of N, P, K, Ca, and Mg in stem and leaf rose to a peak before they declined for the remainder of the growth period. Peaks were in April, May, June, September, or October depending on the part of the plant and the particular mineral. Plants in Forfar, the most eutrophied lake, contained significantly higher levels of tissue N, P, K, and Ca than plants from less eutrophied lakes (Cassar-FRC)

CHEMISTRY, PHYSICS AND EVOLUTION OF ANTARCTIC SALINE LAKES,
H. R. Burton.
Hydrobiologia, Vol 82, p 339-362, 1981. 4 Fig, 2 Tab, 206 Ref.

Descriptors: *Lakes, *Polar regions, Reviews, Nutrients, Seasonal variations, *Saline lakes, *Chemical properties, Hydrology, Evolution, Antarctic.

This review deals with Antarctic saline lakes, discussing specifically the history and evolution of coastal lakes, South Victoria land lakes, the source of water, major ions and dissolved gases present in the water, minor ions present, nutrients and organic matter, light, temperature, stability, water circulation, hydrology, and future work needed in this area. Many of the well developed characteristics of Antarctic saline lakes are related to the extreme seasonal range in solar radiation levels. These characteristics include thick and sometimes permanent ice cover which can ensure long-lasting meromixis, low water temperatures in hypersaline lakes, and usually, oligotrophy. (Baker-FRC)

PHOTOSYNTHETIC ACTIVITY OF PHYTOPLANKTON IN TROPICAL AFRICAN SODA LAKES,
California Univ., Santa Barbara. Dept. of Biological Sciences.
J. M. Melack.
Hydrobiologia, Vol 81, p 72-85, 1981. 8 Fig, 9 Tab, 39 Ref.

Descriptors: *Lakes, *Plankton, *Phytoplankton, *Photosynthesis, Africa, Tropical regions, Soda lakes, *Kenya, Limnology, Diurnal variations, Chlorophyll.

A comparative analysis is presented of the variability of photosynthetic activity during an 18-month period in four Kenyan soda lakes. Three aspects of the photosynthetic activity of phytoplankton are presented: the diurnal and month-to-month changes in photosynthetic activity in two contrasting lakes; the photosynthetic rates and phytoplankton abundances in these two lakes and in additional tropical African soda lakes; and the relations among photosynthetic activity, insolation and efficiency of light utilization for tropical soda lakes. These four lakes encompass most conditions present in the soda lakes of Africa. Lakes Elmenteita and Bogoria are broad, shallow lakes lying in tectonic basins associated with fault scarps. Lakes Simbi and Sonachi occupy small, moderately deep volcanic explosion craters. All four lie in semi-arid basins of internal drainage and their levels fluctuate considerably. The biota includes few species and phytoplankton are usually the major primary producer. To appreciate fully the amplitude and patterns of variability in photosynthetic activity and to determine how ecological factors influence photosynthesis required measurements on time scales from minutes to years. Even in time intervals of only hours, days and months, significant variability was noted. Chlorophyll a concentrations measured in the study varied over 200-fold. While Lake Sonachi had a low rate of photosynthesis, Lake Simbi had exceptionally high rates. A possible explanation is the lower chlorolphyll a concentration in Lake Sonachi, which may be due to a lower rate of supply of nutrients. In general a direct correlation was noted between photosynthetic efficiency of light utilization and photosynthetic rates. (Baker-FRC)

LIMNOLOGICAL STUDY OF A FRESHWATER RESERVOIR, JAMWA RAMGARH (JAIPUR).
Rajasthan Univ. Jaipur (India). Dept. of Botany.
B. Gopal, P. K. Goel, K. P. Sharma, and R. K. Trivedy.
Hydrobiologia, Vol 83, No 2, p 283-294, 1981. 8 Fig, 6 Tab, 20 Ref.

Descriptors: *Limnology, *Reservoirs, Monitoring, Lakes, Water supply, Water quality, Jamwa Ramgarh, Jaipur, *India, Eutrophication, *Semiarid lands.

This paper documents some data on the human activities in the catchment area of, and limnology of a reservoir in the semiarid region of India, along with observations on the recent influences of human activities on the water quality. Jamwa reservoir was constructed by damming the river Banganga, which originates in the midst of the Aravalli ranges in district Jaipur at about 16 km northwest of Manoharpura. The reservoir has a total catchment area of 769 square kilometers which is bounded on all sides by hills of the Aravalli ranges, up to several hundred meters in height. The reservoir is triangular in shape, with maximum length of 7 km and maximum breadth of about 3.5 km. Surface area at the full level is 12.69 square kilometers. Maximum and mean depth are 18 and 4.6 meters, respectively. The reservoir harbors a rich phytoplankton flora; however, it is not rich in fauna. The reservoir is the main source of drinking water supply for the city of Jaipur, supplying about 8 million gallons per day or about 40% of the total water requirement. Forest cover is present in 19.5% of the catchment area, while 25.7% is under irrigated cultivation and the rest is either fallow land or cultivable waste land or not available for agriculture. Accelerated denudation of the vegetation around the reservoir has resulted due to increased numbers of people living there. After remaining oligotrophic during 75 years of its existence, the reservoir is now showing signs of eutrophication. The data collected will help in monitoring the future changes in water quality, an urgent need. (Baker-FRC)

EPILIMNETIC AND HYPOLIMNETIC SYMPTOMS OF EUTROPHICATION IN GREAT MAZURIAN LAKES, POLAND,
Warsaw Univ. (Poland). Chair of Hydrobiology.
Z. M. Gliwicz, and A. Kowalczewski.
Freshwater Biology, Vol 11, No 5, p 425-433, 1981. 5 Fig 1 Tab, 12 Ref.

Descriptors: *Lakes, *Eutrophication, *Poland, *Limnology, Lake morphology, Lake stages, *Great Mazurian Lakes, Epilimnion, Thermal stratification, Oxygen requirements.

An analysis of the long term changes in epilimnetic and hypolimnetic symptoms of eutrophication was performed on data for the Great Mazurian Lakes, a complex of connected lakes with a total area of 310 square kilometers and water flow of low intensity, directed both north and south away from the channel connecting Lake Niegocin with the northern part of the complex. An increase in the rate of eutrophication occurred, beginning in the 1950s with an intensification of agriculture, recreational development and the general expansion of towns. The values of the absolute oxygen deficit, during the analyzed period of time, ranged from 0.037 to 0.132 and from 1950 to 1077 they ranged from 0.049 to 0.132 mg oxygen/square centimeter/day, indicating the sutrophic character of all the lakes studied. For Mamry Polnocne, which is a mesotrophic lake according to SDI data, the value of the absolute oxygen deficit was 0.078-0.125, suggesting it is eutrophic in character. The Secchi disc readings converted to values of SDI show that there was a relatively rapid increase in the trophic state of the lakes studied after 1950, which is comparable with the SDI change in Lake Washington in

LIBRARY U. OF I., URBANA-CHAMPAIGN

the same period. In spite of morphometric similarity, which is important for the intensity of internal loading, smaller lakes advanced their trophic state quicker than larger ones, as each unit of their surface was exposed to more allochthonous input from the neighboring area of their direct drainage basins and from their proportionally larger total drainage basins. Their flushing rates, higher than larger lakes, did not tend to weaken the symptoms of eutrophication. The different thermoclines in smaller vs larger lakes may also be an important factor in determining the rate of hypolimnetic eutrophication. (Baker-FRC)

BIOMASS AND ANNUAL PRODUCTION OF THE FRESHWATER MUSSEL ELLIPTIO COMPLANATA IN AN OLIGOTROPHIC SOFTWATER LAKE,
Cornell Univ., Ithaca, NY.
D. L. Strayer, J. J. Cole, G. E. Likens, and D. C. Buso.
Freshwater Biology, Vol 11, No 5 p 435-440, 1981. 4 Fig. 1 Tab, 22 Ref.

Descriptors: *Lakes, *Ecosystems, *Biomass, Mussels, Aquatic life, Oligotrophic lakes, Trophic cycle, Oligotrophy, *Mirrow Lake, *New Hampshire.

Data on the distribution and abundance of a freshwater mussel in Mirror Lake, New Hampshire, are presented with particular reference to the importance of this mussel in the ecosystem of the lake. Mirror Lake is a small oligotrophic lake in the White Mountains. Its water is clear and soft. From July to September of 1978 and 1979 divers with SCUBA swam transects at 80 meter intervals around the entire lake, and at 40 meter intervals in regions of high clam population density. E. complanata was not abundant in Mirrow lake. It reached maximum density between 2 and 3 meter depths and was most common in gently sloping sandy areas. Only 3% of the biomass and 116% of the annual production are in the younger age-classes. It appears that E. complanata may live to be 16-18 years old in the waters. Therefore, while E. complanata population forms a considerable part of the benthic biomass between 1 and 4 meters depth, it appears to play a trivial role in the functioning of the ecosystem, with its annual production being only about 0.1% of the total macrobenthic production. DOWNCORE VARIATION IN SEDIMENT ORGANIC NITROGEN,
Case Western Reserve Univ., Cleveland, OH, Dept. of Geological Sciences
J. B. Fisher, G. Matisoff, and W. J. Lick.
Nature, Vol 296, No 5855, p 345-347, March 25, 1982. 2 Fig, 15 Ref.

Descriptors: *Nitrogen, *Sediments, *Deposition, *Lake Erie, Lakes, Sedimentology, Lake sediments, Organic compounds, Particulates, Fate of pollutants, *Core sampling, *Temporal distribution.

A procedure for calculating historical depositional flux (loading record) is given for a substance which undergoes post-depositional chemical reaction in a compacting sediment column. Lake Erie sediments were analyzed for organic nitrogen, whose vertical distribution depends solely on the depositional flux of particulate organic nitrogen and the post-depositional rate of microbial decomposition. Net ammonium production was used as a measure of the destruction of particulate organic N. As a result, the rates are minimal, not including possible conversion to other N species. Results indicate that the loading of organic N to the sediments at this locality increased since 1950. The flux of particulate organic N was 0.165 mol per sq m per year in 1820-60 and 0.285 mol per sq m per year in 1974-77, giving a ratio of anthropogenic to natural loading of 0.73. Inclusion of the decomposition factor in calculations of N loading produces lower ratios of apparent anthropogenic contributions of N than obtained in previous work. This method may also be applied to reactive materials such as P and C. (Cassar-FRC)

INITIAL MICROBIOLOGICAL RESPONSE IN LAKES TO THE MT ST HELENS ERUPTION,
Oregon State Univ., Corvallis. School of Oceanography.
J. A. Baross, C. N. Dahm, A. K. Ward, M. D. Lilley, and J. R. Sedell.
Nature (London), Vol 296, No 5852, p 49-52, March, 1982. 2 Fig, 2 Tab, 32 Ref.

Descriptors: *Lakes, *Succession, *Volcanoes, *Water pollution effects, Photosynthesis, Bacteria, Population dynamics, Denitrification, Eutrophication, Oligotrophic lakes, Anaerobic conditions, Hydrobiology, *Microbiological studies, *Mt St Helens.

Little information exists on the early stages in the establishment and succession of aquatic microbial communities and other related chemical and geochemical transformations shortly after a volcanic eruption. The chemical, microbial and hydrothermal responses of lakes affected by the May 18, 1980 eruption of Mount Saint Helens were examined 3 to 4 months after the eruption. The impacted lakes were ultraeutrophic, anaerobic and contained extensive bacterial populations, some not common to the area. By August of 1980, the extent of chemosynthetic , photosynthetic, and heterotrophic activity on the lakes was regulated by both the assimilative and dissimilative nitrogen cycles. Oxygen production by photosynthesis, denitrification and anaerobic oxidation of reduced metals, gases, and organic compounds will aid in restoring the lakes to their normal oligotrophic state.(Geiger-FRC)

KINETICS OF NUTRIENT AND METAL RELEASE FROM DECOMPOSING LAKE SEDIMENTS,
Case Western Reserve Univ., Cleveland, OH. Dept. of Geological Sciences.
G. Matisoff, J. B. Fisher, and P. L. McCall.
Geochimica et Cosmochimica Acta, Vol 45, No 12, p 2333-2347, December, 1981. 7 Fig, 6 Tab, 64 Ref.

Descriptors: *Lake sediments, *Decomposing organic matter, *Nutrients, *Metals, Bottom sediments, Temperature effects, Kinetics, Decomposition, Stochastic process, Model studies, Anaerobic conditions, *Lake Erie, Great Lakes.

Incubation tests with sealed sediment sections from Lake Erie were conducted to determine the rates of anaerobic decomposition for seven depth intervals at three temperatures. The interstitial waters were serially sampled over a period of about 200 days. Concentration increases of bicarbonate, phosphate, ammonium, calcium, magnesium, iron, and manganese in pore water within any given depth interval followed zero order kinetics over the sampling period and exhabited Arrhenius temperature dependency. The rates of release to the pore waters were proportional to the concentrations in the solid phases, indicating first order kinetics overall. The observed release rates decreased exponentially with depth in the sediment due to a corresponding decrease in the amount of metabolizable organic matter and acid hydrolyzable mineral phases. A model was constructed to predict the stoichiometry of the decomposing organic matter and the nature of the hydrogen buffer. The modelling indicates that 60% of the observed bicarbonate release is the direct result of organic decomposition, with the remainder due equally to the dissolution of calcium carbonate mineral phases and to the dissolution of manganese, iron, and magnesium carbonate mineral phases. Kinetic modelling of the observed production rates accurately predicted the vertical profiles of calcium, magnesium, iron, and manganese, but did not quantitatively account for all the concentration differences of carbon, nitrogen, and phosphorus, suggesting that increased depositional flux may partly account for the significant changes in concentrations of these nutrient elements in the near surface sediments. INCORPORATION OF CHEMICAL EQUILIBRIUM, PHYSICO-CHEMICAL REACTIONS AND THE SIMULATION OF INORGANIC QUALITIES IN A RESERVOIR ECOLOGIC MODEL,
Texas Univ. at Austin. Dept. of Civil Engineering.
L. W. K. Lum, N. E. Armstrong, and E. G. Fruh.
Ecological Modelling, Vol 14, No 1, p 95-123, 1981. 22 Fig, 7 Tab, 13 Ref.

Descriptors: *Simulation analysis, *Mathematical studies, *Reservoirs, *Ecology, Chemical reactions, Physicochemical properties, Water quality.

An existing ecological model, LAKECO, was modified and expanded to include physico-chemical reactions including chemical equilibrium between inorganic species and the addition of six inorganic variables that may be of significance in water supply and ecological cycles. LAKECO is a water quality reservoir model consisting of 18 variables which undergo predominantly biochemical-biological reactions. The chemical equilibrium program which was added distributes total concentrations of inorganic variables into free, complexed, and precipitate forms. The six inorganic variables added to the original 18 are calcium, magnesium, iron, silicate, sulfate, and fluorine. The physico-chemical reactions incorporated into the model include precipitation and resolubilization, diffusion of ions from sediments or weathering, complexation, and adsorption of phosphorus onto calcium and iron precipitates and bottom sediments. Two original variables in LAKECO, total dissolved solids and alkalinity, were converted to non-conservative substance. Data from Lake Lyndon B. Johnson, in Texas, were used to calibrate and validate the new, expanded model. The calibration results indicated that chemical equilibrium was a proper assumption on some occasions, such as the simulation of surface phosphorus, but not in others, such as pH. Consideration of the zero-order diffusion of ions from sediments was found to be appropriate in simulating phosphate-phosphorus, ammonia nitrogen, silicate, calcium, magnesium, and iron. The new model allows good simulation of algae. (Carroll-FRC)

EFFECTS OF INCREASED ATMOSPHERIC C02 ON GREAT LAKES,
National Oceanic and Atmospheric Administration, Ann Arbor, MI. Great Lakes Environmental Research Lab.
B. J. Eadie.
In: Workshop on Environmental and Societal Consequences of a Possible C02-Induced Climate Change, Annapolis, Maryland, April 2-6, 1979. Department of Energy Report CONF-7904143, October 1980, p 237-249. 4 Fig, 2 Tab, 17 Ref.

Descriptors: *Carbon dioxide, *Great Lakes, *Calcium carbonate, *Hydrogen ion concentration, *Water temperature, Mathematical models, Model studies, Alkalinity, Productivity, Light penetration, Nutrients, Environmental effects, Ecological effects.

Regular occurrences of green or milky water in several of the Great Lakes has been termed whiting. Seasonal whiting in Lakes Michigan, Ontario and Erie is the result of autogenic precipitation of calcite, caused by the seasonal patterns in temperature and pH. Increasing levels of atmospheric carbon dioxide will lead to laterizations in the aquatic inorganic carbon cycle. An inorganic carbon model based on known PC02 concentrations, constant alkalinity, and constant calcium was

analyzed for the effects of increasing PC02. The model was run at 5 degrees C temperature increments from 0-25 degrees C and at PC02 concentrations of 290 (representing pre-industrial concentrations), 330 (approximate current concentration), 660, 990, and 1980 parts per million. Hydrogen ion concentration will increase with increased carbon dioxide, driving the pH down by approximately 0.3 units by the time the current atmospheric carbon dioxide concentration doubles and by approximately 0.5 at three times the present concentration. At twice the present level, the ratio of the ion activity product of calcium and carbonate divided by the solubility product of calcite will have dropped to 50% of its current value, and at three atmospheres of carbon dioxide the ratio will have dropped below the critical saturation level in Erie and Ontario and be barely supersaturated in Michigan. The overall indication is that the increase in atmospheric carbon dioxide will inhibit the formation of the lakewide whiting of calcium carbonate. The ecological consequences are postulated to be increased productivity due to removal of light backscatter by calcite particles and removal of the mechanism of micronutrient absorption. (Moore-SRC)

THE ECOLOGY OF SOUTHERN CALIFORNIA COASTAL SALT MARSHES: A COMMUNITY PROFILE,
San Diego State Univ., CA. Dept. of Biology.
J. B. Zedler.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-205717, Price codes: A06 in paper copy, A01 in microfiche. Fish and Wildlife Service Report FWS/OBS-81/54, March 1982. 119 p, 49 Fig, 19 Tab, 180 Ref.

Descriptors: *Coastal marshes, *Wetlands, *Ecology, *Marsh management, *Salt marshes, Tidal marshes, Salinity, Flooding, Productivity, Halophytes, Algae, Vegetation, Fauna, Hydrology, Tidal effects, Rainfall, Lagoons, *California.

Southern California coastal marshes are confined to narrow stream outlets along a coastline of rugged topography and continuing geological activity. Tidal sea water is the major source of moisture throughout all but the brief winter wet season. Extreme variations in intertidal soil salinities occur between years of flooding and drought. Lagoon closures cause additional variability in salinity. Freshwater input stimulates germination of most halophytes and flooding events appear to be important for establishment and expansion of species distribution. The net annual productivity of the marsh vascular plants tends to be under 1 kg/sq m/yr. The low-growing, open canopies of vascular plants allow light penetration to the soil surface and subsequent development of lush algal mats. Halophytes probably decompose before being consumed by marsh animals, therby funneling much of their carbon to microbes, while algae are grazed directly by snails, crabs, and topsmelt. Marsh vegetation provides a refuge and food for the native invertebrates, birds and small mammals. Much of the region's wetlands acreage has been destroyed. Management problems include continuing development, reduced tidal circulation, depauperate species lists, and the need to create marsh communities on newly exposed substrates. (Moore-SRC)

MICROBIAL ECOLOGY OF PECTIN DECOMPOSITION IN ANOXIC LAKE SEDIMENTS,
Wisconsin Univ.-Madison. Dept. of Bacteriology.
B. Schink, and J. G. Zeikus.
Journal of General Microbiology, Vol 128, Part 2, p 393-404, 1982. 5 Fig, 2 Tab, 44 Ref.

Descriptors: *Organic matter, *Decomposition, Sedimentation, Sediments, Lakes, *Lake sediments, *Eutrophication, Methanol, Acetate, Pectin, Anaerobic digestion, Bacteria, Lake Mendota, Knaack Lake, *Wisconsin.

The study was performed to characterize the decomposition of pectin and anaerobic pectinolytic population in two freshwater lake sediments and to document the metabolic interactions between prevalent pectinolytic bacteria and other sediment bacteria that account for complete anaerobic mineralization of the polymer. Lake Mendota is a moderately eutrophic, hard water lake, of glacial origin. Knaack Lake is a eutrophic, meromictic lake. The turnover times for pectin biodegradation to methane in sediments incubated at in situ temperatures were much than that observed for glucose or previously reported for acetate. The numbers of pectinolytic anaerobes varied seasonally in both sediments and were highest during the fall after sedimentation of algal blooms and/or leaf detritus. Clostridium butyricum was identified as a prevalent pectinolytic anaerobe in both lakes. In monoculture pectin fermentations, C. butyricum produced methanol, acetate, ethanol and butyrate. Growth stopped in the presence of excess energy source when the pH fell to 4.3. In co-culture pectin fermentations of C. butyricum/Methanosarcina barkeri, methanol and acetate were detected as intermediary metabolites and pectin was completely degraded to methane and carbon dioxide, the pH remaining neutral. During co-culture growth on pectin the concentration of methanogenic substrates is limited by the rate of pectin conversion and the rate of intermediary metabolite consumption. (Baker-FRC)

DO MODEL FOR DISCHARGES FROM DEEP IMPOUNDMENTS,
Tennessee Valley Authority, Chattanooga.
J. M. Higgins, and B. R. Kim.
Journal of the Environmental Engineering Division, Proceedings of the American Society of Civil Engineers, Vol 108, No EE1, p 107-122, February, 1982. 6 Fig, 3 Tab, 34 Ref.

Descriptors: *Model studies, *Dissolved oxygen, *Impoundments, Reservoirs, Oxygen, Mathematical models, Turbines, Biochemical oxygen demand, Temperature effects, Thermal stratification, Seasonal variations, Deep water.

This paper presents a simple model for the annual dissolved oxygen (DO) cycle of releases from the hypolimnion of deep impoundments. This model includes mathematical formulations and rate constant for the processes of biochemical oxygen demand (BOD) decay, atmospheric reaeration, and thermal stratification. The model was used to characterize the DO cycle of releases from 17 Tennessee Valley Authority reservoirs, using three years of weekly DO and temperature data. Rate constants were estimated using the quasilinearization technique for estimating unknown parameters in a system of ordinary differential equations. The results of the study indicate that the model can reasonably simulate annual DO variations of turbine discharges from hypolimnetic waters. Since the model is a simple formulation of complex reservoir processes, it is best suited for preliminary analyses. Future applications of the model would be improved by better data on: inflow BOD and DO concentrations, in-lake BOD variations with time, internally generated BOD, and surface water temperature. The use of weekly flow rates and reservoir volumes and annual rate constant values should also improve the simulation of DO variations from year to year. (Baker-FRC)

HYPANIA INVALIDA IN THE VOLGA RESEVOIRS AND HYDROBIOLOGICAL MONITORING,
N. A. Dzuban, and N. B. Slobodchikov.
Hydrobiological Journal, Vol 16, No 5, p 49-52, 1980. 1 Tab, 22 Ref.

Descriptors: *Hypania, *Reservoirs, *Fish food organisms, Benthic fauna, Invertebrates, *Volga River, *USSR, Self-purification.

Hypania invalida, a polychaete, was introduced as fish fodder into Kuybyshev Reservoir on the Volga River in 1959-67. It was first found near the Kuybyshev Dam in 1977 at a depth of 25 m on silted bottom material at 1000 specimens per sq m. In 1978 it was found at concentrations of 20 specimens per sq on sandy bottom material and 1280 specimens per sq m on silted bottom material. Many specimens were slightly larger (14 mm) than the 12 mm noted in the identification key for the region. Hypania has also been found in the Saratov River and other places in the Volga River system. The organism colonized in a downstream direction from Kuybyushev Reservoir, rather than upstream from the Volga delta, where it is indigenous. In addition to serving as a food resource for fisheries, Hypania and the related Monodacna may help to stabilize the food resources of benthophages. Studies are underway regarding the relation of Hypania to the saprobicity indices and to reservoiir self-purification processes. (Cassar-FRC)

SOME DATA ON THE FAUNA AND ECOLOGY OF METOPIDAE (INFUSORIA) IN KIEV RESERVOIR,
A. A. Koval'chuk.
Hydrobiological Journal, Vol 16, No 5, p 38-44, 1980. 2 Fig, 1 Tab, 34 Ref.

Descriptors: *Species composition, *Lake sediments, *Benthic fauna, Sediments, Reservoirs, Infusoria, Metopids, Invertebrates, *Kiev Reservoir, *USSR.

The composition of the metopid population in Kiev Reservoir indicated that the reservoir is in a satisfactory sanitary state. Altogether 28 species of metopids, 11 of them new to the USSR, were found in 1977-79. The abundance of M. spinosus was greatest in July-September, when water was warmest. A new species, M. tortus pulcher var. tortus, was noted. A new variant was M. setifer var. ovata, and two new forms were M. liminarius f. minima (small and lacking elongated cilia at the posterior) and Brachonella undulans f. tetracilliata (small, truncated posterior and few caudal cilia). The numbers and diversity of these species depend on water quality factors, especially food and temperature factors, but also trace element levels. The metopids are tolerant of hydrogen sulfide. The fact that metopids were not dominant in any instance investigated in associations of Infusoria confirms the satisfactory water quality conditions in this reservoir. (Cassar-FRC)

STATE-OF-THE-ART OF MODELING SURFACE WATER IMPOUNDMENTS,
Nevada Univ. System, Reno. Water Resources Center.
P. A. Krenkel, and R. H. French.
Water Science and Technology, Vol 14, No 1/2, p 241-261, 1982. 8 Fig, 5 Tab, 43 Ref.

Descriptors: *Model studies, *Water quality, *Reservoirs, Lakes, Mathematical models, Hydrodynamics, Water circulation, Aquatic life, Phosphorus, Algae, Dissolved oxygen, Nitrates, Phytoplankton, Ammonia, Zooplankton, Mixing.

Modeling of surface water impoundments, which began in 1920, received impetus in the 1960's from the development of large computers and from the growing awareness of the environment. Since then, reservoir modeling has reached a sophisticated level. One-, two-, and three-dimensional models with many water quality parameters are available. Although the hydrodynamic aspects of the models are reasonably satisfactory, the water quality parameters need further development. In general, models which have been formulated by biologists tend to ignore or simplify the importance of water circulation and mixing, whereas models developed by engineers slight the biological subtleties. The best water quality model lies between the two extremes. When only a few parameters are of interest, simple models may be used in place of complicated, general models. Although most models apply to the pelagic zone, the public is generally interested in the littoral zone, which has

LIBRARY U. OF I., URBANA-CHAMPAIGN

not been subjected to modeling. At this stage in model development the knowledge of physical and biological systems lags behind computer capability. (Cassar-FRC)

THE STRUCTURE OF CRUSTACEAN ZOOPLANKTON COMMUNITIES IN GLACIATED EASTERN NORTH AMERICA,
Guelph Univ., (Ontario). Dept. of Zoology.
J. C. Roff, W. G. Sprules, J. C. H. Carter, and M. J. Dadswell.
Canadian Journal of Fisheries and Aquatic Sciences, Vol 38, No 11, p 1428-1437, November, 1981. 2 Fig, 7 Tab, 38 Ref.

Descriptors: *Glacial lakes, *Zooplankton, *Population dynamics, Lake classification, *Crustaceans, *Species composition, Species diversity, Geology, Regional analysis, North America, Eastern North America.

Since recent studies of the relationship between the structure of freshwater zooplankton communities and physicochemical features of lakes in North America have been made in restricted geographical areas of rather homogeneous character, it has not been possible to determine whether or not species associations tend to vary among regions. Data from 522 lakes of glaciated eastern North America were examined to determine what species coexist and in what combinations and to study possible reasons for the observed patterns of existence. Glacial influence was found to be the primary determinant of zooplankton community structure in these lakes. Use of this criterion resulted in successful discrimination of 82% of the lakes between glacial lakes, to which Diaptomus sicilis, Limnocalanus macrurus, Mysis relicta, and Senecella calanoides were restricted, and nonglacial lakes, of which Cyclops scutifer, Eubosmina longispina, Daphnia pulex, D. catawba, and other species were characteristic. A third large group of common species was distributed throughout the study area with no particular relation to glacial lake influence. There were no clear patterns in community structure with respect to size of zooplankters. Most of the species distributions or abundances were not consistent with the well-known predatory and competitive interactions among zooplankters typical of small lakes and ponds. It is suggested that this resulted partly from the use of large and heterogeneous study area and partly because the biological interactions observed in small lakes and ponds may be less intense in the more physically complex environment of large lakes. Journal of the Water Pollution Control Federation, Vol 52, No 10, p 2425-2431, 2600, October, 1980. 2 Tab, 28 Ref.

Descriptors: *Eutrophication, *Lakes, Rivers, Nutrients, Model studies, Reviews, Environmental effects, Limnology, Lake stages, Lakes, *Chemical composition, *Agricultural runoff, *Sediments.

Basin concepts are reviewed concerning the trophic state of lakes, the eutrophication process, and the role of point and nonpoint sources of nutrients and sediments. The need for specific research on the effectiveness of nonpoint pollution controls is presented. Oligotrophic is the classification applied to those lakes with the smallest concentrations of plant nutrients and the least biological productivity. Eutrophic lakes such as Lake Mendota in Wisconsin have high levels of plant nutrients and high levels of biological productivity. The term mesotrophic is sometimes applied to lakes intermediate between oligotrophic and eutrophic, while ultraoligotrophic and hypereutrophic are sometimes used for lake on the extreme ends of the scale. While many lakes were originally oligotrophic, they have become eutrophic over the years. Lakes influenced by human activity have undergone eutrophication in the period of a few decades, much quicker than lakes out of the reach of man's influence. The high levels of algae in eutrophic lakes make the cost of treatment to obtain desired water quality from the lake much higher. Phosphorus is extremely important in lake restoration programs, not only because it is important as a limiting nutrient, but also because of its chemical nature. Point sources have been responsible for the most publicized cases of cultural eutrophication such as Lake Zurich, Lake Erie and Lake Washington. There are additional problems with lakes that have been heavily loaded for periods of time. Flowing water systems are much more difficult to deal with than lakes. There is little accumulation of nutrients over time as the water is continually moving through the system. Different types of models are used for lakes and rivers. (Baker-FRC)

INTERRELATIONSHIPS IN THE DEVELOPMENT OF THE THREE STRUCTURAL COMPONENTS OF THE PLANKTON IN THE OFF-BOTTOM ZONE OF LAKES,
Belorussian State Univ., Minsk (USSR).
V. A. Babitskiy, T. M. Mikheyeva, and G. A. Inkina.
Hydrobiological Journal, Vol 17, No 1, p 8-14, 1981. 3 Fig, 2 Tab, 19 Ref.

Descriptors: *Lakes, *Phytoplankton, *Zooplankton, *Bacterioplankton, Biomass, Nutrients, Temperature effects, Plankton, Lake beds, *Trophic level, Population dynamics, Limiting factors, Bottom water, Mesotrophic lakes, Eutrophic lakes, Comparison studies, *USSR.

A study was made of zooplankton, phytoplankton and bacterioplankton in a thin zone close to the bottom of the mesotrophic Lake Naroch, the eutrophic Lake Myastro and the highly eutrophic Lake Batorin. Research was conducted in the lakes from May 1970 to May 1971. The mean abundance of all groups of the plankton increased in a regular manner from the mesotrophic Lake Naroch to the highly eutrophic Lake Batorin. Research was conducted in the lakes from May 1970 to May 1971. The mean abundance of all groups of the plankton increased in a regular manner from the mesotrophic Lake Naroch to the highly eutrophic Lake Batorin. The same species were dominant in the zooplankton of all the lakes. Blue-green algae were less abundant in the zone near the bottom of Lakes Naroch and Myastro than in the pelagic zone. In Lake Batorin the bulk of the phytoplankton biomass in the zone near the bottom was largely Ceratium and blue-green algae, but in the pelagic zone exclusively blue-green algae. Throughout the study the biomass of fodder phytoplankton in Lakes Naroch and Myastro altered only slightly, invariably remaining at a fairly low level. The biomass of the filter feeders was higher over the vegetation season than that of fodder phytoplankton, and in Lake Myastro was also higher than that of bacterioplankton. The low biomass values of fodder phytoplankton and their slight fluctuations in Lakes Naroch and Myastro confirm the previous suggestion that interrelationships between the zooplankton and its food are evidently strained in the zone near the bottom of the lakes. Detritus must play an appreciable role in the consumption of the zooplankton of these areas. The temperature factor has appreciably influenced the development of first-order and second order consumers, of fodder phytoplankton, and of bacterioplankton in Lake Myastro. Food may not be a limiting factor in the development of planktonic filter feeders in highly eutrophic lakes. (Baker-FRC)

AN ELECTRON MICROSCOPIC STUDY OF THE FORMS OF BACTERIA IN THE SURFACE FILM OF THE WATER,
Akademiya Nauk SSSR, Moscow. Inst. Biologii Vnutrennykh Vod.
Ye. A. Lepilova, and V. A. Gavrilova.
Hydrobiological Journal, Vol 17, No 1, p 27-30, 1981. 2 Fig, 7 Ref.

Descriptors: *Reservoirs, *Bacteria, *Surface water, Lakes, Water quality, Seasonal variations, *Microbiological studies, Air-water interfaces, *USSR.

A method is presented for producing bacterial preparations for electron microscopy studies by placing electron microscope grids in the surface film of the water to pick up fouling. This method was used to study the microflora of the surface film. Research was carried out at the Rybinsk Reservoir in May, August and September of 1978. Water samples were taken at six stations in the open part of the reservoir and in the inshore zone. The studies showed that the bulk of the bacteria in the surface film of the water, both in the inshore zone and in the open part of the reservoir, and rod-shaped bacteria and cocci, members of the genus Caulobacter. Rod-shaped forms constitute the overwhelming majority in the surface film in all experiments. Most often they are in clusters, sometimes joined into chains, but solitary forms are also encountered. Rare species were more frequently found in the inshore zone than in the central part of the reservoir. Only filamentous forms were found in the open part of the reservoir. Smaller rod-shaped bacteria were sometimes parasitic on filamentous forms. The most varied microflora in the surface film of the water in the inshore zone was recorded in August, which is also the time of maximum production of organic matter through the photosynthesis of algae. (Baker-FRC)

THE FORMATION OF WATER QUALITY IN THE SHALLOWS OF A SOUTHERN RESERVOIR (DNIEPER-KRIVOI ROG CANAL) UNDER THE INFLUENCE OF BEDS OF HIGHER AQUATIC VEGETATION,
Akademiya Nauk URSR, Kiev. Inst. Hidrobiologii.
N. B. Korsak, and V. K. Myakushko.
Hydrobiological Journal, Vol 17, No 1, p 37-42, 1981. 2 Tab, 17 Ref.

Descriptors: *Water quality, *Reservoirs, Lakes, Aquatic plants, Biomass, Seasonal variation, *Yuzhnoye Reservoir, USSR.

Changes in water quality were investigated in the Dnieper-Krivoi Rog Canal reservoir, called the Yuzhnoye. The reservoir has a water area of 11.03 square kilometers, a volume of 57.3 million cubic meters, and a mean depth of 5.2 meters, with a maximum depth of 26 meters. Aerial-aquatic plants play the major role both in overgrowth and in the formation of primary production. The effect of higher water plants on water quality was investigated. The water quality in the shallows of Yuzhonoye Reservoir extensively involved higher water plants and was dependent on the composition of the communities, their productivity, the stage of phenological development of the plants and the extent of the flow through the overgrown areas. The most favorable hydrochemical conditions during the period of study were noted in the highly productive beds of aerial-aquatic vegetation, through which there was no flow. When macrophyte production was moderate and flow through the shallows was adequate, water quality in the communities of aerial-aquatic vegetation did not alter appreciably, and in the summer was often better than in the open areas. The effect of the submerged vegetation on the hydrochemical regime of the shallows during the vegetation period was generally positive, with the oxygen saturation of the water in the weed beds reaching 135%, the content of dissolved biogenic matter being lower than in the plant-free areas as a result of its active consumption by plants, the concentration of organic compounds not exceeding the standards for maximum permissible concentrations, and partial decalcination of the water in a number of instances in the absence of carbon dioxide and high pH values. PLANKTONIC INFUSORIA AS INDICATORS OF THE EXTENT OF ORGANIC POLLUTION IN AZERBAIDZHANIAN RESERVOIRS,
Akademiya Nauk Azerbaidzhansjoi SSR, Baku. Inst. Zoologii.
I. K. Alekperov.
Hydrobiological Journal, Vol 17, No 1, p 57-42, 1981. 5 Fig, 1 Tab, 11 Ref.

Descriptors: *Reservoirs, *Water quality, Oxygen, Oxidation, Aquatic plants, *Plankton, Azerbaidzhanian Reservoirs, Indicators, *Organic pollution, Pollutant identification, *USSR.

An account is given of the extent of organic pollution in three Azerbaidzhanian reservoirs - the Mingechaur, Varvara and Dzheyranbatan. Date was collected seasonally from 1972 through 1974. Sixty species of Infusoria were recorded as indicators of different degrees of saprobicity in the plankton of all the reservoirs investigated. Each reservoir belonged to the beta-meso and alpha-mesosaprobic zones as regards the degree of organic pollution, as the indicators of these zones accounted for between 64 and 76% in each of them. The main reason for the heavier pollution in the upper part of the reservoir is the water of the rivers supplying it. The pollution of the Khanabad part was due to rotting organic matter accumulating in it. The upper part of the Varvara Reservoir was the cleanest part of the reservoirs examined. The inshore zone of the Varvara Reservoir was the most polluted, being used by the inhabitants for watering cattle. The number of indicator species of the alpha-meso-polysaprobic zone found here was 8%. The middle part of the Dzheyranbatan Reservoir was the cleanest part of this reservoir. Of the total of indicator Infusoria recorded in it, 78% belong to the oligo-beta-mesosaprobic zones. Indicators of the alpha-meso-polysaprobic zone were also recorded in the inshore area of these parts, in the upper part accounting for 4% of the total, in the lower part for 6%. Consequently, ecological analysis of the Infusoria of Mingechaur, Varvara and Dzheyranbatan reservoirs shows that their water belongs in the main to the mesosaprobic zone, that is, there is adequate oxygen in the water, and mineralization takes place by the total oxidation of organic matter. SALT AND TRACE ELEMENT COMPOSITION OF THE WATER OF LAKE MALINOVOYE (ALTAI TERRITORY); AS A HABITAT OF ARTEMIA SALINA,
Lvov Univ., (USSR).
N. S. Yalynskaya, and I. V. Strubitskiy.
Hydrobiological Journal, Vol 17, No 1, p 73-77, 1981. 2 Tab, 23 Ref.

Descriptors: *Chemical composition, *Lakes, Aquatic life, Crustaceans, *Salinity, Sodium chloride, Magnesium, Sediment, *Lake Malinovoye, *Trace elements, Aquatic environment, Water quality, Water analysis, Biological samples, Sediment samples, *USSR.

Samples of water, bottom material and specimens of Artemia salina were collected from Lake Malinovoye during July of 1978 and 1979. The water was quite highly saline, with the principal salt being sodium chloride. The water was shown to contain 20 components, the bottom material 26. Artemia was represented by four physiological groups in the samples from the lake. Females molting with undiscarded exuviae, females between the period of molts and oviferous, sexually mature females in the period between molts without eggs, and mature molted females with soft integuments made up the four groups. The morphological structures responsible for maintaining the water and salt balance are manifested in response to the distinctive ionic-salt composition of the habitat of the halobiont Artemia salina. Under the conditions of Lake Malinovoye, the development and growth of Artemia salina took place with a small quantity of calcium cation and in the absence of the salt, calcium carbonate. As in other water bodies, A. salina in Lake Malinovoye needed sodium chloride as its principal salt. Magnesium was apparently a vitally important ion for Artemia salina. (Baker-FRC)

MUTUAL FLOCCULATION OF ALGAE AND CLAY: EVIDENCE AND IMPLICATIONS,
Science and Education Administration, Durant, OK. Southern Plains Watershed and Water Quality Lab.
Y. Avnimelech, B. W. Troeger, and L. W. Reed.
Science, Vol 216, No 4541, p 63-65, April 2, 1982. 2 Fig, 14 Footnotes.

Descriptors: *Flocculation, *Algae, *Clays, Aggregates, Turbidity, Anabaena, Chlorella, Chlamydomonas, Sedimentation, Clarification, Lakes, Water quality management.

Algae-clay aggregates were formed in the presence of a critical concentration of electrolyte, 0.005 M for CaC12 and 0.02 M for NaCl. Algae were not flocculated in the absence of clay under the conditions studied. Flocculation patterns of the algae were biphasic. In the first phase (at the lower clay concentrations) increasing the clay concentrations sharply increased the degree of flocculation. Further increases in clay concentration after a certain point produced little additional flocculation. The maximum ratios of clay to algae in the particles were 1.7, 0.2, and 0.03 (wet weight) for Anabaena, Chlamydomonas, and Chlorella, respectively. Eglena gracilis had little tendency to flocculate. The variability in flocculating potential among the different algae is probably affected by composition and properties of the cell wall, extent and type of secretions, physiological conditions, and age. Algal-clay flocculation may be useful in water quality management. For example, turbid water could be clarified by promoting algal growth, or algal-rich water could be clarified by addition of clay to the water. Sedimentation of algae leads to a downward displacement of nutrients. Filter feeders such as silver carp can only use particles larger than 20-50 microns; therefore, algae too small to be trapped may be used if aggregated with clay. (Cassar-FRC)

BIOASSAYS AND THE ALGAL POPULATIONS OF HASTINGS LAKE, ALBERTA, CANADA,
Zurich Univ. (Switzerland). Hydrobiology-Limnology Station.
F. Schanz.
Water Research, Vol 16, No 4, p 441-447, April, 1982. 4 Fig, 2 Tab, 42 Ref.

Descriptors: *Bioassay, *Biomass, *Algal growth, *Anabaena, *Eutrophic lakes, *Limiting nutrients, Eutrophication, Cyanophyta, Lakes, Iron, Phosphorus, Nutrients, Temperature, Weather, Aquatic populations, Species composition.

A set of experiments was carried out to investigate the success of introducing Anaebaena clones into untreated waters of Hastings Lake, Alberta, Canada to establish this species as the dominant indigenous plankton population. Experiments were carried out in the summer of 1978 on the biomass development of the eutrophic lake, and bioassays were performed on untreated water, water inoculated with Anabaena flos-aquae, and filtered or autoclaved water. Bioassays on untreated Hastings Lake water showed good correlations with the biomass developments in the lake. Nutrient levels were assessed by bioassays with unialgal cultures in filtered or autoclaved water samples. During the summer months, iron and/or phosphorus seemed to be important limiting nutrients for algal growth in Hastings Lake. Results of competition experiments failed to render conclusive information upon which to base predictions about the future development of Anabaena on the lake. Some effects of weather on algal production are discussed. (Geiger-FRC)

INDOLES IN THE DECOMPOSITION PRODUCTS OF CERTAIN BLUE-GREEN ALGAE,
Akademiya Nauk URSR, Kiev. Inst. Hidrobiologii.
V. V. Arendarchuk.
Hydrobiological Journal, Vol 17, No 1, p 50-53, 1981. 1 Fig, 1 Tab, 7 Ref.

Descriptors: *Algae, *Decomposition, Eutrophication, Degradation, Indoles, Lakes, Dissolved solids, Seston.

An attempt was made to elucidate the dynamics of the concentration of indole compounds and to identify such compounds in the decomposition products of seston collected in a water body during the mass bloom of blue-green algae. The research was conducted on seston consisting as to 80-90% of Microcystis aeruginosa and Aphanizomenon flos-aquae. The content of indoles in the water increased following the decomposition of the organic matter of dying cells of blue-green algae to a certain level, after which it declined as a result of mineralization. Temperature had an appreciable effect on the decomposition of the algal mass and the formation of indole-containing compounds. Chromatographic separation of the decomposition products of the algal mass showed that various substances entered the water in appreciable amounts. Among the decomposition products of the algal mass were found two indole compounds and one phenol compound. One of the indole compounds found on the chromatograms was verified, it was established that zones corresponding to indole compounds stimulated the growth of wheat coleoptiles. The maximum stimulation was given by the indole-acetic acid zone. The zone corresponding to the phenol compound inhibited growth. Consequently, phenol and indole compounds entered the water on the death and post mortem decomposition of the organic matter of the blue-green algae that cause the algal bloom. These compounds have a growth-stimulating activity. (Baker-FRC)

THE IMPORTANCE OF LACUSTRINE ZOOPLANKTON TO THE FEEDING CAPACITY OF THE LIZHMA LAKE-RIVER SYSTEM (BASIN OF LAKE ONEGA).
Akademiya Nauk USSR, Petrozavodsk. Inst. of Biology.
A. N. Kruglova.
Hydrobiological Journal, Vol 17, No 1, p 15-20, 1981. 4 Fig, 2 Tab, 24 Ref.

Descriptors: *Lakes, *Zooplankton, Rivers, Lake Kedra, Kedra River, Lake Tarasm, Fish food, Plankton, Biomass, Aquatic fauna.

The object of this study was to establish the part played by zooplankton carried out of lakes in providing food resources for the spawning and growing reaches of salmon rivers. Research was carried out in the lower reach of the Lizhma, covering 4.3 km from its outflow from Lake Kedra to the mouth, location of the main spawning grounds of valuable food fishes such as salmon, whitefish, and trout. Observations and data were collected during the open water period of May through October in the years 1972 and 1973 and every 10 days at 6 permanent stations during 1976 and 1977. A total of 78 species of plankton organisms were found in the investigated part of the Lizhma River. There were more crustaceans and Rotatoria, members of the weekbedbank complex, in the plankton of the river reaches than in the lake reached. These species are particularly plentiful in calm reaches of the river with developed aquatic vegetation. The potamoplankton in the Lizhma River mostly originate from the lakes. The main sources for the development of the plankton are Lake Kedra and Lake Tarasm. The plankton fauna of the river rapids consist mainly of Rotatoria, the smaller Copepods, and some species of Cladocera. The species and quantitative indices of the zooplankton vary with distance from the outflow from the lakes. The parts of lake-river system below the lakes are the most productive. An appreciable amount of plankton is carried out of Lake Kedra and lake Tarasm. The plankton flow is greatest in the main in the summer months. Zooplankton carried out of the lakes is utilized by juvenile fishes and benthic invertebrates, and helps to increase the density of the drift, the main food for juvenile salmon. (Baker-FRC)

EVALUATION OF FOURTEEN TROPHIC STATE INDICES FOR PHYTOPLANKTON OF INDIANA LAKES AND RESERVOIRS,
Notre Dame Univ., IN. Dept. of Biology.
P. F. Sullivan, and S. R. Carpenter.
Environmental Pollution, Series A, Vol 27, No 2, p 143-153, February, 1982. 4 Fig, 2 Tab, 18 Ref.

Descriptors: *Lakes, *Phytoplankton, *Reservoirs, *Trophic level, Water quality, Water analysis, Lake classification, Algal growth, Eutrophication, Plankton, Indiana, Statistical analysis, Diversity indices, Species diversity.

Principal components analysis (PCA) was used to examine the relationships of fourteen phytoplankton trophic state indices to forty-two samples from Indiana lakes and reservoirs. The goals of the study were to determine which groups of indices were redundant and which indices were most diagnostic of the various classes of sample that emerged from the PCA. Twenty-seven Indiana lakes and reservoirs, each downstream of a sewage treatment plant outfall, were sampled in the spring, summer and autumn of 1973. The results indicated that diversity indices were not useful of trophic classification, as they are not monotonically related to degree of eutrophication and require more data for their calculation than other indices. Nygaard's indices were often undefined, and therefore unusable, because the denominator was zero. Palmer's genus index was more sensitive to differences among samples than Palmer's species index. Of the indices examined, two were relatively useful - Palmer's genus index, which reflects the abundance of eutrophic indicator genera, and the concentration of the most abundant taxon, which is sensitive to bloom samples. MICROSCALE PATCHINESS OF NUTRIENTS IN PLANKTON COMMUNITIES,
Michigan Univ., Ann Arbor.
J. T. Lehman, and D. Acavia.
Science, Vol 216, No 4547, p 729-730, May 14, 1982. 1 Tab, 15 Footnotes.

Descriptors: *Nutrients, *Algae, *Population dynamics, Phosphorus, Plankton, Phytoplankton, Zooplankton, Daphnia, Chlamydomonas, Lakes, Species composition.

Unstirred cultures containing zooplankton (Daphnia) labeled with P33 and algae (Chlamydomonas) were compared with stirred cultures by autoradiographic techniques. In the unstirred vessels, which simulated the natural microscale (mm or less) patchiness of nutrient distribution, algae augmented their cell quota of P33 as much as 12% per encounter. Apparently the nutrient patches produced by excretion of P by the zooplankton exist long enough for algae passing through to absorb more nutrients than do algae outside the patches. These conditions favor development and survival of algal types which can quickly acquire nutrients from the short-lived nutrient patches existing in otherwise nutrient-poor waters. (Cassar-FRC)

AGE, SPACING AND GROWTH RATE OF TAMARIX AS AN INDICATION OF LAKE BOUNDARY FLUCTUATIONS AT SEBKHET KELBIA, TUNISIA,
University Coll., London (England). Dept. of Botany and Microbiology.
F. B. Goldsmith, and N. Smart.
Journal of Arid Environments, Vol 5, No 1, p 43-51, 1982. 6 Fig, 2 Tab, 9 Ref.

Descriptors: *Lakes, *Tamarisk, Phreatophytes, Tunisia, Saline lakes, Population densities, Floods, Boundaries, Water boundary, Sebkhet Kelbia, Wildlife habitats, Evapotranspiration.

Measurements were made of the population structure, growth rates and spacing of tamarisk in the northeast corner of Sebkhet Kelbia, a shallow evaporative lake in central Tunisia. The area chosen for intensive study is a considerable fringing zone of tamarisk; the zonation was clear. This was also near the point where outflow occurs during the large flood events. The tamarisk varied considerably in density, intensity of grazing and height, so a stratified method of sampling was employed to investigate the range of variation. The oldest bushes in the sample examined were only 8 years old. The distribution of stems between age classes approximated a normal curve with a mean aroung 1974/75 and a range of 6 years. This type of distribution would only be expected if the tamarisk were being harvested or had been destroyed in a catastrphic event such as the 1969 and 1973 floods. Since the colonization and age structure of the population postdates the 1969 and 1973 floods, it can be assumed that the areas were last inundated during these events. The annual growth rates since that time indicate a period of relative inactivity from the hydrological viewpoint, with continued shrinkage of the lake and encroachment of the fringing lake vegetation. Areas of dead Typha which mark former lake levels were being colonized by tamarisk as evidence of this encroachment. Tamarisk in the future is likely to increase in extent, and its ecological effects upon the area deserve further attention. (Baker-FRC)

2I. Water In Plants

WATER MANAGEMENT OF WHEAT IN HEAVY CLAY SOILS OF MADHYA PRADESH,
Jawaharlal Nehru Agricultural Univ., Jabalpur (India). Dept. of Soil Science and Agricultural Chemistry.
S. S. Tomar, R. K. Gupta, and A. S. Tomar.
Indian Journal of Agricultural Sciences, Vol 51, No 7, p 493-497, July, 1981. 1 Fig, 3 Tab, 9 Ref.

Descriptors: *Water use efficiency, *Irrigation, *Crop yield, *Wheat, Clays, Irrigation efficiency, *India, Grain crops, Water management, Soil-water-plant relationships.

Wheat (Triticum aestivum-Linn. emend. Thell.) grown on heavy clay soil of central Madhya Pradesh, India, was irrigated 1 to 4 times during the growing season during a study in 1974-77. Treatments were: T1 irrigation at preemergence; T2, T1 plus 1 irrigation at crown root initiation; T3, T2 plus 1 irrigation at tillering; and T4, T3 plus 1 irrigation at flowering. The crop receiving 4 irrigations (t4) produced the highest yield of grain, 43.45 q per ha. Lowest yield was produced by treatment T1,26.70 q per ha. Water use efficiency was highest with treatment T1 (105-123 kg per ha per cm) and decreased with increasing mumber of irrigations to 97-105 kg per ha per cm for T4. This was a result of the higher residual moisture left unused in the profile and deep percolation losses. Moisture regimes of less than 40 cm in a 150 cm profile adversely affected water used by the crop. (Cassar-FRC)

EFFECT OF MOISTURE LEVELS IN VEGETATIVE AND REPRODUCTIVE PHASES OF WINTER-SOWN MAIZE ON GRAIN YIELD, IRRIGATION REQUIREMENT AND WATER-USE EFFICIENCY,
Rajendra Agricultural Univ., Samastipur (India).
D. P. Singh, S. D. Prasad, U. K. Prasad, and N. N. Sharma.
Indian Journal of Agricultural Sciences, Vol 51, No 12, p 861-864, December, 1981. 1 Fig, 3 Tab, 14 Ref.

Descriptors: *Irrigation requirements, *Water use efficiency, *Corn, Irrigation efficiency, Soil-water-plant relationships, *India, Grain crops, Crop yield.

Maize (Zea mays Linn.) was planted in the winters of 1976-77 to 1978-79 at Dholi, India, to determine the irrigation requirements. Irrigations were scheduled when the available soil moisture (ASM) in the top 0-30 cm soil layer reached 70,50, and 30% in the vegetative and reproductive phases separately. Maximum yield of 57.3-68.8 q per ha was produced by irrigation at 70% ASM in the vegetative phase and 50 or 70% ASM in the reproductive phase. Water use efficiency increased with the drier regimes. These results suggest that the optimum irrigation regime for winter-sown maize in this region would be 5 or 6 irrigations (intervals of 30-34 days) to produce 70% ASM in the vegetative phase and 50-70% ASM in the reproductive phase. This recommendation applies for the seasonal rainfall range of 66-173 mm. (Cassar-FRC)

EFFECT OF PLANT POPULATION AND NITROGEN ON WATER-USE EFFICIENCY OF

PEARLMILLET IN THE ARID ZONE OF WESTERN RAJASTAN,
Central Arid Zone Research Inst., Jodhpur (India).
A. Krishnan, S. D. Singh, and A. S. R. A. S. Sastri.
Indian Journal of Agricultural Sciences, Vol 51, No 12, p 865-870, December, 1981. 1 Fig, 3 Tab, 4 Ref.

Descriptors: *Irrigation, *Water use efficiency, *Fertilizers, Millet, *India, Crop yield, Grain crops, Water management, Nitrogen, Arid lands, Evapotranspiration, Consumptive use, Soil-water-plant relationships.

Seasonal consumptive use by rainfed pearl miller (Pennisetum typhoides Burm. f.) was studied at 10 and 20 cm plant spacing and nitrogen additions of 0 to 120 kg per ha. The experiment was conducted during 1974, 1975, and 1977 when annual rainfall amounts in this arid region of India were 67%, 178%, and 95% of normal (366.9 mm). Seasonal consumptive uses at 10 cm spacing were 223, 253, and 247 mm at N additions of 0, 60, and 120 kg per ha, respectively. Seasonal consumptive uses at 20 cm spacing were 213, 210, and 289 mm at the same N addition regimes, respectively. Water use efficiency (in kg grain per mm evapotranspiration) was highest with 60 kg N per ha (5.38) followed by 4.83 for 120 kg per ha N, and 3.54 at no added N. Water use efficiencies for the two plant spacings were almost the same. Results of predictions of the soil moisture storage with consideration of initial soil moisture storage by the climatic water budget method (Thornthwaite and Mather, 1955) agreed well with observed values, but the conventional prediction method underestimated soil moisture storage. STORM SEDIMENT CONCENTRATIONS AS AFFECTED BY LAND USE, HYDROLOGY, AND WEATHER,
West Virginia Univ., Morgantown. Dept. of Chemical Engineering.
F. H. Verhoff, and S. M. Yaksich.
Journal of Environmental Quality, Vol 11, No 1, p 72-78, January-March, 1982. 6 Fig, 3 Tab, 15 Ref.

Descriptors: *Sediment transport, *Storms, *Suspended sediment, Temperature effects, Seasonal variations, Erosion, Rainfall-runoff relationships, Lakes, *Lake Erie, Water pollution sources.

A study is reported of suspended sediment transport to Lake Erie. Two types of analyses are reported: time variations and hydrologic variations. The principal variable used is an average suspended sediment concenration, computed by summing the suspended sediment transported during a given time period, divided by the water discharge during the same time period. From the total phosphorus data on the Sandusky River, it is concluded that 3 or 4 years of data are not sufficient to determine the effect of point source abatement in an agricultural watershed. Hydrology and weather are the major factors affecting the storm average suspended sediment concentration in the Maumee River at Waterville. Important variables are maximum discharge during the storm, storm duration, water temperature and high wind average for the days since the previous storm. Raindrop impact and rain energy do not explain the variation in the suspended sediment concentration at Waterville on the Maumee River. Maximum dischage has a positive influence on storm average suspended sediment concentration because higher velocities are able to carry greater concentrations of sediment. Storm duration is significant in a negative way on concentration because longer storms tend to have declining stages during which the suspended sediment concentration is lower. Water temperature's positive influence may be due to microbial activity in the river bottoms. The dependency of the average storm suspended sediment concentration on the maximum discharge is nearly the same for all seasons of the year. (Baker-FRC)

THE INFLUENCE OF WATER SALINITY ON PALUDAL EROSION PROCESSES,
New Orleans Univ., LA. Dept. of Geography.
N. L. Froomer.
Journal of Geology, Vol 90, No 2, p 179-185, March, 1982. 5 Fig, 2 Tab, 19 Ref.

Descriptors: *Salinity, *Soil erosion, Water quality, River banks, *Mississippi River Delta, Geology, Marshes, Aquatic plants, *Environmental effects, *Salt marshes.

This paper investigates the influence of water salinity on marsh erosion processes. Laboratory experiments were constructed to determine the influence of water salinity on the erodibility of three different coastal marsh soils from the Lake Pontchartrain-Lake Borgne area of southeastern Louisiana. Site 1 was located in a brackish environment where vegetation is dominated by the grass Spartina alterniflora, producing a coarse but interconnected underground matrix of large diameter roots and rhizomes. Site 2 was in a slightly brackish environment near the mouth of Bayou Lacombe with Spartina patens dominating the vegetation, producing a tightly interwoven underground matrix of thin, fibrous rhizomes. The third site was in a slightly brackish to fresh environment with spartina cynosuerdes vegetation, which does not produce an underground framework of interconnected rhizomes. Although the influence of salinity varied in different soils, erodibility generally decreased as the water salinity was increased from 0 to 10%. The field evidence from the Mississippi River delta indicates that most rapid erosion occurred where and when water salinity was lowest, given the same wave energy. Salinity is believed to influence marsh erodibility due to the influence of salt concentration of electrical field interactions among soil colloids. (Baker-FRC)

BED LOAD FLUCTUATION: APPLICATIONS,
Institute of Water Conservancy and Hydroelectric Power Research, Beijing (China).
H. Qiwei, and H. Mingmin.
Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 108, No HY2, p 199-210, February, 1982. 2 Tab, 4 Ref.

Descriptors: *Sediment transport, *Mathematical studies, *Bed load, *Fluctuations, *Sediment erosion, Sediment load, Sedimentation, Model studies, Mathematical equations, Streambeds, Stream profiles, Stream erosion, Sediments, Erosion, *Particle size, Sampling.

Research on the mechanism of bed load movement is important in interpreting hydrological measurements. The sampling duration under various conditions should be recorded so that the measured transport rate may be obtained with sufficient accuracy. Derivations are examined for the variance and coefficient of variation of transport rate for uniform and nonuniform sand with determinate and random size distributions over a pebble bed. Due to frequent deposition and erosion, along with apparent sorting, the particles become more uniform at certain locations. The relationship between the coefficient of variation of transport rate for the whole cross section of the stream bed and that of local points was derived. This information will aid in estimating the accuracy available from the sampling duration used. (Geiger-FRC)

EROSION BY SUBMERGED CIRCULAR JETS,
Alberta Univ., Edmonton. Dept. of Civil Engineering.
N. Rajaratnam.
Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 108, No 2, p 262-267, February, 1982. 1 Fig, 1 Tab, 5 Ref.

Descriptors: *Erosion, *Jets, *Mathematical studies, *Froude number, Scour, *Nozzles, Mathematical equations, Sand, Flow velocity, Plane flow.

Recent work on the erosion of sand beds by plane submerged air and water jets in the impinging as well as wall jet modes shows that, for the air-sand and water-sand systems, even though the functional dependence of the ratios of maximum depth of erosion to impingement height and the diameter of the jet at the nozzle of the densimetric Froude number might be of the same kind, there are considerable differences in the magnitude of these relationships. A series of experiments was performed on the erosion of sand beds by submerged circular impinging water jets to see if this kind of difference exists for circular jets. Similarities were found in the air-sand and the water-sand system, but significant differences concerning the depth, as well as the radial extent of the scour hole were also noted. A relationship involving the densimetric Froude number, the impingement height, and the diameter of the jet at the nozzle influenced the erosion of sand beds by impinging submerged circular water jets, as well as the maximum depth of erosion, the radial extent of the scour hole, and the height of the ridge that forms around the scour hole. For some values of this relationship, the depth of scour in the water-sand system would be smaller while the radial extent of erosion would be much smaller. (Geiger-FRC)

DISTRIBUTION OF SUSPENDED SEDIMENT IN THE PATUXENT RIVER, MARYLAND DURING DREDGING OPERATIONS FOR CONSTRUCTION OF A PIPELINE,
Columbia Gas System Service Corp., Wilmington, DE.
E. Onuschak, Jr.
Bulletin of the Association of Engineering Geologists, Vol 19, No 1, p 25-34, 1982. 8 Fig, 6 Ref.

Descriptors: *Dredging, *Sediment transport, *Spoil disposal, Suspended sediment, Turbidity, Patuxent River, Maryland, *Pipelines, Trenches, Erosion, Sediment erosion, Tidal rivers, Estuaries, Environmental effects, *Patuxent River, Maryland.

Dredging in the Patuxent River, Maryland, offered an opportunity to study the environmental impact of temporary, underwater storage of spoil during trench construction in a tidal river. An 8 ft deep trench was dredged with a clam shell-type dredge mounted on a barge. Spoil was deposited in piles underwater within range of the dredge boom. Backfilling from the spoil pile was done after the pipeline had been installed. Suspended solids were measured on the surface, at mid-depth, and at the bottom at 4 sites in the deepest part of the channel before, during, and after dredge operations. During dredging the average turbidity of the water increased a maximum of 2 times (50-70 mg per liter) over the baseline level (30-50 mg/per liter). After dredging was completed, turbidity returned to baseline levels within 3 weeks. Monitoring downstream of the spoil piles indicated that the sediment from the piles was not being significantly eroded. (Cassar-FRC)

ERODIBILITY OF SELECTED SOILS AND ESTIMATES OF SEDIMENT YIELDS IN THE SAN JUAN BASIN, NEW MEXICO,
Geological Survey, Denver, CO. Water Resources Div.
R. M. Summer.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-195744, Price codes: A03 in paper copy, A01 in microfiche. Geological Survey Water-Resources Investigations 81-44, 1981. 33 p, 10 Fig, 9 Tab, 31 Ref.

Descriptors: *Soil erosion, *Small watersheds, Simulated rainfall, *Land reclamation, *Sediment yield, Soil management, Coal mining, *New Mexico, *San Juan basin, Sediment transport.

Onsite rainfall-simulation experiments were conducted to derive field-erodibility indexes for rangeland soils and soils disturbed by mining in coal fields of northwestern New Mexico. Mean indexes on rangeland soils range from 0 grams (of detached soil) on dune soil to 121 grams on wash-transport zones. Mean field-erodibility-index values of soils disturbed by mining range from 16 to 32 grams; they can be extrapolted to nearby coal fields where future mining is expected. Because field-erodibility-index data allow differentiation of erodibilities across a variable landscape, these indexes were used to adjust values of K, the erodibility factor of the Universal Soil Loss Equation. Estimates of soil loss and sediment yield were then calculated for a small basin following mining. (USGS)

Descriptors: *Soil erosion, *Model studies, *Terrain analysis, Surface flow, *Stochastic process, Soil surfaces, Flow, Surface runoff, Surface water, Surface drainage, Mathematical studies, Stochastic hydrology, Probabilistic process, Model testing, Topography, Prediction, Rills, Channels, Rill erosion, Gully erosion, Rainfall intensity, Slope degradation, Runoff, *Erosion rates.

Research was carried out to develop a mathematical model of the progress of erosion on sloping ground that would be able to account for the irregular topography of the ground surface, the overland flow pattern compatible with the topography, and the erosion and topographic change due to flow. The model computes the erosion and flow pattern, and the rill-interrill characteristics as a function of time and space. It also includes simplified mechanisms to simulate ponding, deposition, and failure of side slopes of rills. Sensitivity analysis of the model revealed that the use of shorter time intervals gives better erosion rate estimates. Surface elevation randomness has a significant effect on erosion rate reduction; surfaces with greater random variations evidence smaller erosion rates, while rill pattern randomness appeared to have a smaller effect. The effects of slope gradient, slope length, and rainfall intensity were also examined. The results are in general agreement with experience. (Zielinski-MAXIMA)

ON MEASURING TIME-AVERAGED VELOCITIES IN OPEN CHANNEL FLOW,
Copenhagen Univ. (Denmark). Dept. of Geography.
J. Bartholdy.
Sedimentology, Vol 29, No 1, p 91-94, February, 1982. 2 Fig, 7 Ref.

Descriptors: *Open channels, *Flow measurement, Velocity, Channels, Canals, Mathematical studies, Sediment transport, Sedimentation.

The problem of determining the necessary length of time over which velocities must be measured in open channel flows in order to secure accurate time-averaged velocities is addressed. The method presented was tested against the data from velocities measured at 60 second intervals at 10 points in a vertical on the Columbia River below Priest Rapids Dam. The measurements were carried out simultaneously and were continued for 66 minutes. Depth at the measuring station was 6.4 meters, the 66 minute mean velocity was 1.0 meters/second, and the Nikuradse roughness and friction velocities calculated from the velocity profile were 0.31 meters and 0.07 meters/second, respectively. The experiments and theory applied to determine the necessary equations were based on a steady and uniform two-dimensional flow. The results are therefore limited to cases in which these conditions are fulfilled or can be approximated. Where inhomogeneities in the water column play an important role, such as in stratified estuaries, or where discontinuities in the cross-profile cause large eddies to appear, the measuring time must necessarily be much longer than predicted herein. In spite of these limitations, the method as described can find use in many natural channels and offers the possibility of making a qualified choice of the optimal measuring time when working in the field. SOURCES OF SEDIMENT-INDUCED REDUCTIONS IN WATER QUALITY APPRAISED FROM CATCHMENT ATTRIBUTES AND LAND USE,
H. W. Anderson.
Journal of Hydrology, Vol 51, No 1-4, p 347-358, May, 1981. 7 Tab, 9 Ref.

Descriptors: *Suspended sediments, *Sediment load, Catchment areas, Land use, Water quality, Sediment discharge, Factor analysis, Mathematical studies, Streamflow, Landslides, Geology.

In order to develop estimates of sediment discharge from catchments or of the expected contribution of parts of catchments to sediment discharge or to sediment-induced reductions in water quality, it is first necessary to evaluate the sources and causes of suspended sediments. Suspended sediment measurements from 61 catchments in California were used to relate suspended sediment discharge to the following ten catchment attributes: steep grasslands, landslide potential, watershed steepness, rain-snow frequency, streamflow volume, poor logging, watershed shape, unconsolidated sediment, geology (including faults), and forest fires. Suspended sediment was normalized by using long-term streamflow estimates for each catchment. Factor analysis showed no confounding among the ten variables. The ten variable regressions had an explained variance of 73%. The contribution of watershed factors to this explained variance in suspended sediment discharge was as follows: landslide potential, 31%; steep grasslands, 11%; streamflow and rain-snow frequency, 12%; poor logging, 9% and other, 10%. Catchment shape was the least important variable, while differences in landslide classes produced the greatest differences in sediment discharge. A separate analysis was used to develop a basis for calculating landslide classes from catchment attributes. The results of these analyses were applied to the Redwood Creek Basin in California to separate natural from accellrated sediment discharge and sediment concentration in the basin. It was concluded that thee relationships found in this study have direct application to thee evaluation of sedimentation problems and control in northern California and control in northern California and may give some first approximation to evaluations in other areas. SEDIMENTARY RECORD OF RAINFALL VARIATIONS ON A SUB-HUMIC LAKE,
New Univ. of Ulster, Coleraine (Northern Ireland). Limnology Lab.
B. Rippey.
Nature (London), Vol 296, No 5856, p 434-436, April 1, 1982. 4 Fig, 26 Ref.

Descriptors: *Lake sediments, *Sedimentology, *Climatology, Dayat Afougach, Morocco, Precipitation, Prediction, Rainfall, Sedimentation rate.

A 1.3 m sediment core was obtained from the deepest part of a lake, Dayat Afougach, Morocco, on September 25, 1979. Fourier analysis was performed on the dry weights of 1 or 2 cm sections and the annual rainfall totals from 1958-79 for Ifrane, 23 km from the lake. At a wave length of about 12 cm (range 8-18 cm) an annual sedimentation cycle was evident. This was consistent with previous evidence that in this Mediterranean-type climate sediment particle size is largest (highest dry weight) in the wet season immediately following the dry season. The relationships of organic matter, Na, Mg, and Fe to dry weight show that particle size is responsible for the variations in dry weight. The 12 cm annual sedimentation rate is also consistent with data from other lakes in similar environmental settings. Lower sediment dry weights were found at core depths corresponding to 1971-74, low rainfall years. Study of lake sediment dry weights may give information on precipitation patterns in areas where climatological records are not available. (Cassar-FRC)

HINDERED BEDLOAD SETTLING AS A MODEL OF SAND BED PLANATION BY WATER WAVES,

Coastal Engineering Research Center, Fort Belvoir, VA.
R. J. Hallermeier.
Nature, Vol 297, No 5861, p 53-55, May 6, 1982. 1 Fig, 1 Tab, 23 Ref.

Descriptors: *Sediment transport, *Bed load, *Wave action, Planation, Sand, Fluid flow, Flow velocity, Oscillatory waves, Settling velocity, River beds.

Sand bed planation is converted to a threshold effect in hindered settling with increasing concentration of noncohesive sediment moving near the bed. The equation derived was consistent with laboratory results using 15 sediments with buoyance indexes of 19 to 137,000, corresponding to quartz sand in water. The viewpoint in this paper is different from that of Bagnold's criterion for planar bed occurrence for unidirectional and oscillatory flows. (Cassar-FRC)

EROSION FROM MOUNTAIN SNOWPACK MELT,
Utah State Univ., Logan. Watershed Science Unit.
G. E. Hart, and S. A. Loomis.
Journal of Soil and Water Conservation, Vol 37, No 1, p 55-57, January/February, 1982. 1 Tab, 3 Ref.

Descriptors: *Snowmelt, *Erosion, *Surface runoff, Snowpack, Mountains, Soil erosion, *Utah, Slopes, Runoff, Infiltration.

Soil loss from clear-weather snowmelt was minimal on four test plots located on a bare mountain slope in Utah. Erosion was 2.8-10.6 pounds per acre on the plots with 11% slope and 7.8-23.6 pounds per acre on the plots with 32% slope. Maximum snowpack in 1978 was 12 inches water equivalent; in 1979, 16 inches; and in 1980, not measured. Soil loss was twice as great in 1979 as in 1978, although the snowmelt runoff volume in 1979 was three times greater. Most of the snowmelt infiltrated into the soil. Only a small percentage of the water equivalent in the snowpack appeared as surface runoff, up to 1.3% on the gentle slope and 1.0-3.5% on the steep slope. The small soil losses do not warrant inclusion of the snowmelt factor in the universal soil loss equation in mountain terrain with a moderately deep snowpack which persists throughout the winter. (Cassar-FRC)

BEDLOAD AND SIZE DISTRIBUTION IN PAVED GRAVEL-BED STREAMS,
Minnesota Univ., Minneapolis. St. Anthony Falls Hydraulic Lab.
G. Parker, P. C. Klingeman, and D. G. McLean.
Journal of the Hydraulics Division, Proceedings of the American Society of Civil Engineers, Vol 108, No HY4, p 544-571, April, 1982. 14 Fig, 5 Tab, 20 Ref.

Descriptors: *Bed load, *Gravel, Streams, Sediment transport, Sediment load, Mathematical equations, Model studies, *Oregon, Oak Creek.

An attempt has been made to describe, based solely on field data, bedload relations for natural, paved gravel-bed streams. Data gathered from Oak Creek, Oregon were used to study the size distribution of bedload in paved gravel-bed streams. Similarity analysis suggests that once the pavement is broken, essentially all sizes are rendered of roughly equal mobility. This implies that for poorly-graded gravels only one grain size is required to characterize total bedload as a function of Shields stress, and that not much extra accuracy can be gained by calculating the bedload for each size range separately and summing. It also suggests that the bedload size distribution should approximate that of the pavement. The first implication was used to develop a simple means of predicting total bedload in gravel bed streams in conjunction with data from Oak Creek, the Elbow River, and other streams. The method approximates accuracy for streams with moderate to steep slopes that are not dominated by sand throughput load. The second implication would appear to apply in terms of annual sediment yield form gravel-bed streams that are not dominated by throughput load. A reanalysis of the Oak Creek data reveals that higher flows favor coarser bedload material. As concerns the relation of Meyer-Peter and Muller, its performance regarding the field data presented in this study is poor. There also appears to be no way to adjust the relation in terms of an effective grain size to bring it into accord with the data. Thus, it is not recommended. (Baker-FRC)

TRAP EFFICIENCY STUDY, HIGHLAND CREEK FLOOD RETARDING RESERVOIR NEAR KELSEYVILLE, CALIFORNIA, WATER YEARS 1966-77,
Geological Survey, Menlo Park, CA. Water Resources Div.
L. F. Trujillo.
Geological Survey Water-Supply Paper 2182, 1982. 15 p, 7 Fig, 8 Tab, 12 Ref.

Descriptors: *Trap efficiency, *Detention reservoirs, *Sediments, *California, Water storage, Sediment transport, Particle size, Chemical analysis, *California, Lake County, Kelseyville, Highland Creek Reservoir.

This investigation is part of a nationwide study of trap efficiency of detention reservioirs. In this report, trap efficiency was computed from reservoir inflow and outflow sediment data and from reservoir survey and outflow data. Highland Creek Reservoir is a flood retarding reservoir located in Lake County, near Kelseyville, California. This reservoir has a maximum storage capacity of 3,199 acre-feet and permanent pool storage of 921 acre-feet. Mean annual rainfall for the 14.1-square-mile drainage area above Highland Creek Dam was 29 inches during the December 1965 to September 1977 study period. Resultant mean annual runoff was 17,100 acre-feet. Total reservoir inflow for the 11.8-year study period was 202,000 acre-feet, transporting an estimated 126,000 tons (10,700 tons per year) of suspended sediment. Total reservoir outflow for the same period was 188,700 acre-feet, including 15,230 tons (1,290 tons per year) of sediment. Estimated trap efficiency for the study period was 88 percent, based on estimated sediment inflow and measured sediment outflow. Reservoir surveys made in December 1965 and April 1972 revealed a storage capacity loss of 35.8 acre-feet during the 6.3-year period. Ccomputed by using an estimated specific weight, this loss represents 54,600 tons of deposited sediment. Sediment outflow during the same period was 8,890 tons. Trap efficiency for the survey period was 86 percent. (USGS)
W82-05852

POTENTIAL SEDIMENT PRODUCTION WITHIN VEGETATIVE COMMUNITIES IN OREGON'S BLUE MOUNTAINS,
Oregon State Univ., Corvallis. Dept. of Rangeland Resources.
J. C. Buckhouse, and R. E. Gaither.
Journal of Soil and Water Conservation, Vol 37, No 2, p 120-122, March/April, 1982. 1 Fig, 1 Tab, 4 Ref.

Descriptors: *Sediment yield, *Erosion rates, *Vegetation effects, *Forest hydrology, Sagebrush, Grasslands, Meadows, Alpine regions, Pine trees, Fir trees, Juniper trees, Sspruce trees, Trees, Larch trees, Blue Mountains, Oregon, Infiltrometers, Soil erosion.

Potential sediment losses were determined in 10 natural ecosystems in Oregon's Blue Mountains using a Rocky Mountain infiltrometer simulating rainstorms of 10 cm per hour. Potential sediment production levels (kg per ha) in various ecosystems were: juniper, 1572; sagebrush, 1284; grassland, 431; spruce-fir, 217; ponderosa pine, 183; alpine, 140; Douglas fir, 109; lodgepole pine, 36; meadow, 22; and larch, 15. As ecological condition class and/or vegetative productivity class changed within an ecosystem, significant changes in potential sediment production occurred. Condition class refers to tree size in forested units and to condition (poor to fair) in other ecosystems. Productivity refers to pounds per acre of forage or cu ft per acre per year of wood produced, Class I being most productive and Class IV, least productive. In general, sediment losses increased as the condition class changed from good toward poor and decreased with improvement in productivity. (Cassar-FRC)

SEDIMENT MIXING AND ACCUMULATION RATE EFFECTS ON RADIONUCLIDE DEPTH PROFILES IN HUDSON ESTUARY SEDIMENTS,
Lamont-Doherty Geological Observatory, Palisades, NY.
C. R. Olsen, H. J. Simpson, T.-H. Peng, R. F. Bopp, and R. M. Trier.
Journal of Geophysical Research, Vol 86, No C11, p 11020-11028, November 20, 1981. 10 Fig, 31 Ref.

Descriptors: *Sediment distribution, *Estuarine environment, Estuaries, Sediments, Sedimentation, Hudson River, Rivers, Radioactivity.

A comparison was made of the measured anthropogenic radionuclide profiles in sediment cores from the Hudson River estuary by using known input histories of radionuclides to the estuary and mixing coefficients which decreased exponentially with depth in the sediment. The effective mechanical mixing rates of the upper layers of sediments appeared to be of the order of 0.25 to 1 square centimeter per year or less. These rates do not appear to alter substantially the depth of subsurface activity peaks owing to reactor releases in areas with accumulation rates of 1 cm per year or greater. Thus the subsurface peak radionuclide activities in Hudson sediments appear to be useful as first order time stratigraphic reference levels for estimating rates and patterns of sediment accumulation. Variations in the observed sediment radionuclide depth profiles from trends that would be expected from the history of fallout delivery and reactor releases can be used as indicators of the various processes regulating particle transport and accumulation along the axis of the Hudson estuary. COMPARISON OF PHOTOCHEMICAL BEHAVIOR OF VARIOUS HUMIC SUBSTANCES IN WATER: I. SUNLIGHT INDUCED REACTIONS OF AQUATIC POLLUTANTS PHOTOSENSITIZED,
Environmental Research Lab., Athens, GA.
R. G. Zepp, G. L. Baughman, and P. F. Schlotzhauer.
Chemosphere, Vol 10, No 1, p 109-117, January, 1981. 3 Fig, 2 Tab, 17 Ref.

Descriptors: *Humic acids, *Organic compounds, *Chemical reactions, *Photochemical reactions, Fulvic acids, Organic matter, Disulfoton, Aniline, Pentadiene, Dimethylfuran, Kinetics, Fate of pollutants, Solar radiation, Oxygenation, Comparison studies.

Organic chemicals which do not undergo photochemical reactions in distilled water degraded when exposed to sunlight in water containing natural or commercial humic substances. Chemicals tested were disulfoton, aniline, 2,5-dimethylfuran, and cis-1,3-pentadiene. Photoproducts were generally the same for each chemical regardless of the source of humic material. Kinetic data indicated that rate constants were within a factor of 2 in solutions of humic substances of different origin. Disulfoton and 2,5-dimethylfuran underwent photosensitized oxygenation to disulfoton sulfoxide and diacetylethylene, respectively. The half life of disulfoton ranged from 4 hours during summer to 10 hours during winter. The major photoproduct of aniline was azobenzene; the half life of aniline in May was 4-8 hours. Cis-1,3-pentadiene isomerized to trans-1,3-pentadiene. (Cassar-FRC)

COMPARISON OF PHOTOCHEMICAL BEHAVIOR OF VARIOUS HUMIC SUBSTANCES IN WATER: II. PHOTOSENSITIZED OXYGENATIONS,
Environmental Research Lab., Athens, GA.
R. G. Zepp, G. L. Baughman, and P. F. Schlotzhauer.
Chemosphere, Vol 10, No 1, p 119-126, January, 1981. 3 Fig, 2 Tab, 10 Ref.

Descriptors: *Humic acids, *Chemical reactions, *Organic compounds, Fate of pollutants, Dimethylfuran, Organic matter, *Photochemical reactions, Kinetics, Solar radiation, Oxygenation, Comparison studies.

The photochemical oxygenation of 2,5-dimethylfuran (DMF) in water was investigated using humic substances from natural sources and commercial sources as photosensitizers. At low DMF concentrations the reactions were first order with respect to DMF. Reaction rate constants were directly proportional to the average light intensity and to the concentration of humic substances. Rate constants were independent of hydrogen ion activity from pH 5 to 10. Above pH 10 the rate constants decreased with increasing pH. Ultraviolet and blue radiation were most influential in the photosensitization. Rate constants for this reaction calculated from computer-simulated sunlight intensities agreed well with the observed values. Since the ratios of sunlight rate constants to total visible solar irradiance (400-700 nm) were nearly constant, it may be possible to calibrate the rate constants in terms of units such as foot candles. (Cassar-FRC)

THE OCCURRENCE AND ORIGIN OF METHANE IN SOME GROUNDWATER FLOW SYSTEMS,
Waterloo Univ. (Ontario). Dept. of Earth Sciences.
J. F. Barker, and P. Fritz.
Canadian Journal of Earth Sciences, Vol 18, No 12, p 1802-1816, December, 1981. 5 Fig, 4 Tab, 62 Ref.

Descriptors: *Methane, *Carbon isotopes, *Geochemistry, *Groundwater, Organic matter, Landfills, Sanitary landfills, Chemical reactions, Biodegradation.

Groundwaters from 10 areas in Canada and the U.S. contained methane at levels from below the detection limit of 10 to the minus 7th power mol per liter to 0.0063 mol per liter. The origin of the methane was determined from carbon isotope ratios. Of 28 samples whose stable carbon isotope ratios were measured, 5 samples with delta C13 values greater than -45 o/oo were of thermocatalytic origin (nonbiological, chemical production). The common biogenic methanes had delta C13 values less than -60 o/oo. Biogenic methanes from sanitary landfill sites had intermediate values of -38 to 56 o/oo and were easily distinguished from normal biogenic methanes. The biogenic methanes in this study appeared to derive from organic matter. The carbon isotope ratios of dissolved methane and total inorganic carbon were not controlled by equilibrium fractionation processes but by kinetic isotope effects. (Cassar-FRC)

NITROGEN AND PHOSPHORUS DYNAMICS IN HOT DESERT STREAMS OF SOUTHWESTERN U.S.A.,
Arizona State Univ., Tempe. Dept. of Zoology.
N. G. Grimm, S. G. Fisher, and W. L. Minckley.
Hydrobiologia, Vol 83, No 2, p 303-312, 1981. 5 Fig, 2 Tab, 46 Ref.

Descriptors: *Streams, *Deserts, Arid lands, *Nitrogen, *Phosphorus, Chemical properties, Nutrients, *Arizona, Nitrates, Phosphates, *Gila River basin.

The potentials for nutrient limitation in streams in hot, arid and semi-arid regions of Arizona were examined by determining the dynamics of nitrogen and phosphorus in 38 different systems of the Gila River drainage. Thirty-eight low elevation streams and stream segments were sampled in Southern Arizona, primarily in summer 1979. Most sites were in the Sonoran Desert, with some in a transition zone between the Sonoran and Chihuahuan Deserts and others in Interior Chaparral. Perennial flowing waters in the Sonoran Desert region usually exist because they originate in highlands outside arid zones. Typical Arizona surface waters are carbonate dominated. Highest nitrogen concentrations were associated with stream sources and flood waters which enter stream channels at elevated nitrogen levels after recent contact with nitrate rich terrestrial soils. Soluble reactive phosphate was not significantly higher in sources and floods than in free-flowing streams, and in the latter, concentrations were usually greater than 0.5 microM. Nitrogen is a likely candidate for nutrient limitation in free flowing streams of this region. Nitrate, but not soluble reactive phosphate, was correlated with periphyton abundance and net production in reaches originating at enriched sources. Rapid uptake by periphyton lowered nitrate concentrations to potentially limiting levels; however, soluble reactive phosphate was seldom depleted and was apparently controlled by other factors. Thus, in spite of the presence of nitrate enriched sources in desert streams, nitrogen may be reduced to limiting levels before phosphorus. (Baker-FRC)

METAL ION COMPLEX FORMATION CONSTANTS OF SOME SEDIMENTARY HUMIC ACIDS WITH ZN(II), CU(II) AND CD(II),
Lehigh Univ., Bethlehem, PA. Dept. of Chemistry.
M. L. Sohn, and M. C. Hughes.
Geochimica et Cosmochimica Acta, Vol 45, No 12, p 2393-2399, December, 1981. 1 Fig, 3 Tab, 52 Ref.

Descriptors: *Humic acids, *Bottom sediments, *Metal complexes, Zinc, Copper, Cadmium, *Lake sediments, *Marine sediments, Chemical analysis.

Humic acids form one of the most important source/sink systems for metal ions in the soils and bottom sediments in both fresh and saline waters. A substantial portion of the metal ions presented in soils and sediments is bound in labile form to humic acids. A size exclusion chromatography technique as used to determine metal ion complex formation constants for several sedimentary humic acids derived from a fresh water lake and several coastal marine environments. Zinc(II), copper(II), and cadmium(II) were selected are representative of pollutant metals in coastal areas. Only one type of binding site was observed in all cases. Elemental composition of the sedimentary humic acids, except that the nitrogen content was sifnificantly higher in the sedimentary humic acids. Other chemical properties of the sedimentary humic acids were consistent with previously reported findings. Spectroscopic measurements indicated that the sedimentary humic acids may have contained significant amounts of polysaccharide compunds which were not removed by conventional separation and purification processes, but analysis showed only very low levels of polysaccharides present in the humic acids. (Carroll-FRC)

THE EFFECTS OF ADSORBED HUMIC SUBSTANCES ON THE SURFACE CHARGE OF GOETHITE (ALPHA-FE00H) IN FRESHWATERS,
Freshwater Biological Association, Cumbria (England).
E. Tipping, and D. Cooke.
Geochimica et Cosmochimica Acta, Vol 46, No 1, p 75-80, January, 1982. 4 Fig, 1 Tab, 20 Ref.

Descriptors: *Organic matter, *Electrical properties, *Iron oxides, Surface water, Ions, Cations, Calcium, Magnesium, *Electrophoresis, Adsorption, Shear, *Chemical reactions.

Electrophoresis has been used to demonstrate that a negative charge is conferred on a variety of types of particles in freshwaters by the adsorption of organic matter. A previous study of a single lake showed that the magnitude of the negative charge conferred on the surface by adsorbed humic substances was determined not only bu the amount of humics adsorbed, but also by coadsorbed bivalent calcium (Ca) and magnesium (Mg) ions. This study attempted to generalize these earlier results by measuring electrophoretic mobilities of a model iron oxide, goethite, added to solutions in which humic and cation concentrations were varied systematically over wide ranges, to surface water samples from three more British lakes having varied chemical properties, and to artificial lakewaters with compositions based on those of the natural samples. These electrophoretic measurements showed that goethite particles added to lake surface water samples become negatively charged because of the adsorption of humic substances. The magnitude of the negative charge was found to decrease with increasing concentrations of the bivalent cations Ca(2 plus) and Mg(2 plus). It is suggested that the large molecular size of the humics causes the plane of electrokinetic shear to be some distance from the oxide surface, with the shear potential attributable to ionized humic functional groups not involved in adsorptive interactions with the oxide surface. This model accounts qualitatively for (a) the effects of Ca(2 plus) and Mg(2 plus) in terms of interactions with the humic functional groups in the shear plane; (b) the pH-dependence of the electrophoretic mobilities; and (c) the lack of effect of inorganic phosphate and silicate on the mobilities, despite the shared ability of these solutes to compete with humics for adsorption at natural concentrations. Descriptors: *Plankton, *Carbon cycle, Ecosystems, Aquatic environment, *Nutrients, Cycling nutrients, Flooding, Phytoplankton, Suspended solids, Bacteria, South America, Brazil, Peru, *Amazon River.

The biological and chemical characteristics of the various plankton environments of the Amazon River system were examined in an effort evaluate the influence of exogenous carbon and nutrients on plankton metabolism and the importance of respiration and phytoplankton production to the carbon dioxide equilibria in the riverine and floodplain waters. The study results indicated that large-scale events such as flooding can have a major impact upon the cycling of carbon and nutrients in these aquatic ecosystems. The major factors influencing primary production during high water appeared to be nutrient concentrations in the mouthbays and varzea (floodplain) lakes and high levels of suspended matter in the Amazon mainstream. Bacterial densities, carbon-14-acetate uptake rate constants, and plankton carbon: ATP ratios implied that heterotrophic microbiota were important components of the plankton communities in riverine waters. High particulate carbon: nitrogen ratios (20:1) indicated that terrestrial organics were important to metabolic activity in all Amazon surface waters. The observed supersaturation of Amazon waters by carbon dioxide was similar to observations for other rivers of the world. The primary source of the carbon dioxide is most likely decomposing organic matter in planktonic and benthic environments of the rivers, lakes, and flooded terrestrial lowlands. These findings support the hypothesis that respiratory input of carbon dioxide balanced by evasion is sufficient to explain high carbon dioxide vapor pressures in the Amazon, but further examination is recommended. Experimental data on activity coefficients of ions and salts in seawater were compared with theoretical predictions obtained from several methods. Differences between experimental and theoretical activity coefficients of ions and salts did not exceed 0.03-0.05 (5-10% relative) and were within the limits of accuracy in determining the instability of ion pairs. The greatest differences were seen for strongly associated salts. Therefore, chemical reactions should be calculated with respect to the least associated salts. (Cassar-FRC)

SULFATE BUDGET AND MODEL FOR SULFATE CONCENTRATIONS IN STREAM WATER AT BIRKENES, A SMALL FORESTED CATCHMENT IN SOUTHERNMOST NORWAY,
Central Insitute for Industrial Research, Oslo (Norway).
N. Christophersen, and R. F. Wright.
Water Resources Research, Vol 17, No 2, p 377-389, April, 1981. 3 Fig, 4 Tab, 44 Ref.

Descriptors: *Sulfates, *Streams, *Forest watersheds, Watersheds, Forest soils, Soil types, Catchment areas, Catchment basins, River basins, Chemical composition, Solute transport, Birkenes catchment, *Norway.

The flux of sulfate into and out of the Birkenes catchment is calculated from data collected over a 6 yr period. Ground vegetation is 58% blueberry-bracken community, 28% pine community, and 7% fen and bog forest. Soils consist of 79% podzols, 17% peaty soils and 4% bare rock. Bedrock is biotite-granite. The annual sulfate flux is about 5-10 times higher than would be expected. The result is an acidification of stream water and an increased leaching of base cations from the soil. The concentration of sulfate in stream water at Birkenes shows a characteristic pattern of high levels in the first stormflow following a dry summer period and low levels in baseflow. Sulfate is assumed to accumulate in the uppermost soil layers due to dry deposition and evapotranspiration of rainwater. Mineralization of other sulfur compounds is included indirectly. In the lower mineral soil layers, adsorption/desorption of sulfate is assumed to occur. The ability of this simple model to simulate sulfate concentrations in stream water suggests that the model quantitatively accounts for these processes. (Baker-FRC)

Descriptors: *Ion transport, *Thermodynamics, *Salts, *Equilibrium, *Chemical reactions, *Hydration, Ionic interference, Anions, Cations, Ions, Salinity, Seawater, Ultrasonics, Baseline studies, Chemical analysis, Water properties, Research needs.

A summary is provided on research which was undertaken to define the nature and properties of aqueous ionic species and to understand the relationship between individual ion hydration and classical thermodynamic properties. The research, experimentally, relied heavily on relaxation methods (particularly, ultrasonic absorption (UA) to bridge the gap between dynamic processes and equilibrium considerations. Studies with UA were made on aqueous solutions of tetraalkylammonium halide salts as a function of concentration and temperature. Combining the UA results with dielectric relaxation and equilibrium thermodynamics made it possible to quantitatively describe such systems in terms of the coupled equilibrium processes. Partial molal volumes and compressibilities at infinite dilution are directly related to the structural effects of the salts in water. Measurements of sound velocity in salt solutions down to 0.0001 molal were made for developing ionic compressibility data. In addition, several aqueous salt equilibria were studied and a lanthanide nitrate complexation model was quantitatively treated. Application in this case was directed towards the interaction between multivalent cations and various anions which lead to many important association equilibria in sea water. (Zielinski-MAXIMA)

EXCHANGE OF MARINE SODIUM FOR CALCIUM DURING CHEMICAL WEATHERING IN THE ISLE AUX MORTS RIVER BASIN, NEWFOUNDLAND,
Canada Center for Inland Waters, Burlington (Ontario).
M. E. Thompson.
Geochimica et Cosmochimica Acta, Vol 46, No 3, p 361-365, March, 1982. 3 Fig, 3 Tab, 15 Ref.

Descriptors: *Weathering, *Salts, *Ion exchange, Precipitation, Sea salt, Sodium, Calcium, *Isle aux Morts, *Newfoundland, Rivers, Chlorides, Sodium chloride, Chemical composition, Cation exchange.

Sea salt corrections must be applied in coastal river water chemistry studies prior to calculating weathering rates and evaluating the impact of acid precipitation. Sea salt corrections applied to data on contents of major seawater ions (Ca, Mg, Na, K, chloride, sulfate and bicarbonate) in the Isle aux Morts River, Newfoundland, using Cl(-) as the indicator species produced several negative values of Na(+). These were most numerous in winter when sea salt concentrations were high. Periods of negative Na(+) corresponded with periods of higher than usual Ca(2+) concentrations, suggesting that the higher sea salt levels may promote an exchange reaction in the soils: calcium silicate + 2Na(+) = sodium silicate + Ca(2+). Analysis of atmospheric precipitation in this region showed that sea salt levels were highest in winter and early spring. (Cassar-FRC)

Sulfur species and trace metals were determined in pore waters of sediments from a salt marsh near Lewes, Delaware. Three cores were collected during the summer of 1978, one to study the analytical methods, one a day before the monthly inundation and one at the end of the inundation period. The most important of the many inorganic and organic sulfur compounds detected at significant levels were hydrogen sulfide, polysulfides, and thiosulfates. Equilibria between hydrogen sulfide, thiols, and the polysulfides depend on the redox conditions. Bacterial sulfate reduction is dominant in the pore waters except at the surface during dry conditions, where oxidation of hydrogen sulfide produces thiosulfate and sulfide. Inorganic polysulfides are formed from the reaction of hydrogen sulfide with elemental sulfur. Organic polysulfides are the result of the reaction of thiols with elemental S and/or organic polysulfides. Thiols are produced by reactions of organic matter with hydrogen sulfide and/or elemental S. Thiosulfates are yielded by hydrogen sulfide oxidation and the hydrolysis of polysulfides and pyrite. It is suggested that the redox couple sulfide/polysulfide is a good indicator in this situation. Concentrations of Cu and Fe in the pore waters are controlled by formation of metal sulfides. Cu is probably complexed by organic matter, possibly a thiol. (Cassar-FRC)

Descriptors: *Particulate matter, *Seasonal variation, *Chemical precipitation, Sampling, *Esthwaite Water, *United Kingdom, Suspended solids, Anaerobic conditions, *Lakes, Organic carbon, Iron, Manganese, Phosphorus, Sulfur, Magnesium, Potassium, Barium, Calcium, Phytoplankton, Hypolimnion, Oxidation-reduction potential, Chemical reduction, Geochemistry, Adsorption, Iron oxide.

A study of ten water column profiles in Esthwaite Water (England's Lake District) between April and November 1979 revealed that particle chemistry in this highly productive lake is controlled by three biogeochemical cycles. A large excess of particulate P, S, Mg, Ca, Ba, and K is generated in situ in the epilimnion by growth of phytoplankton in spring and summer. Concentration variations follow that of particulate organic carbon. This particulate buildup is a result of oxidative precipitation of ferric oxide, which causes adsorption and/or coprecipitation with the Mg, Ca, and other elements. The formation of ferric oxide is, in turn, a result of the dissolved ferrous iron released as the hypolimnion becomes anoxic. The onset of anoxic conditions in the hypolimnion also induces an increase in bacterial populations in the bottom water. As reducing conditions become more intense after July, the iron oxide particles with the associated particulate Mg, Ca, etc., solubilize. Just before the lake overturns, large populations of bacteria and the formation of FeS particles control the concentration of excess particulate carbon, S, P, Mg, K, and Ca. The results of this study point out the importance of understanding the biogeochemical cycles in designing sampling schedules for monitoring a lake's natural or man-modified chemistry. (Cassar-FRC)

FLUORAPATITE AND FLUORITE SOLUBILITY CONTROLS ON GEOTHERMAL WATERS IN YELLOWSTONE NATIONAL PARK,
Wisconsin Univ.-Madison. Water Chemistry Lab.
R. E. Stauffer.
Geochimica et Cosmochimica Acta, Vol 46, No 3, p 465-474, March, 1982. 4 Tab, 42 Ref.

Descriptors: *Phosphates, *Solubility, *Geothermal studies, Fluorapatite, *Chemical composition, *Yellowstone National Park, Wyoming, Equilibrium, Hot springs, Chlorides, Fluorite, Calcium fluoride, Geochemistry, Saturation, Geysers.

Stauffer and Thompson's (1978) data on the phosphate contents of six differing classes of Yellowstone National Park geothermal waters were analyzed by a computer program, WATEQF. The near-boiling high-chloride waters (Class I) were at or near saturation with respect to fluorapatite. The 16 springs in this category had fluorapatite saturation indexes ranging from -3.2 to +4.9 (average +0.9). The strongly positive indexes were associated with the high alkaline conditions resulting from adiabatic cooling near the surface. Spring waters diluted with meteoric water (Class II) had lower chloride content, lower pH, and were undersaturated with fluorapatite in spite of high phosphate and Ca concentration. The travertine-depositing mixed water springs (Class VI) were super-saturated with fluorapatite at the surface and at or near saturation with hydroxylapatite. The supersaturation may be a result of kinetic inhibition of apatite crystallization by the high concentrations of Mg(++) and bicarbonate as well as the lower water temperatures. With respect to fluorapatite, Class III waters (hot, near neutral condensed vapor springs) were also weakly supersaturated, Class IV waters (acid Norris mixed water springs) were strongly undersaturated, and Class V waters (bicarbonate buffered mixed water springs) were weakly undersaturated. The hottest spring waters (90-100 C at the surface) were undersaturated with calcium fluoride at the surface, probably as a result of fluorite equilibration at the higher temperatures (> 200 C) in deeper reservoirs. RADIUM CONTENT AND THE 226RA/228RA ACTIVITY RATIO IN GROUNDWATER FROM BEDROCK,
Institute of Radiation Protection, Helsinki (Finland).
M. Asikainen.
Geochimica et Cosmochimica Acta, Vol 45, No 8, p 1375-1381, August, 1981. 2 Fig, 2 Tab, 17 Ref.

Descriptors: *Radioactivity, *Groundwater, *Bedrock, *Aquifers, *Radium, Geologic formations, Chemical composition, Radium radioisotopes, Isotope fractionation, *Finland, Wells, Leaching, Groundwater dating.

The concentrations of Ra228 and the Ra226/Ra228 ratio in water from drilled wells situated in different parts of Finland were investigated. Areas with unusually highly radioactive water were emphasized in this study, and Ra228 was analyzed mainly in samples with an elevated Ra226 content. These measurements were supplemented by additional analyses of Ra226 and Ra228 carried out on water from some drilled wells situated in areas with no known radioactivity anomalies in groundwater. The concentration of Ra228 was independent of the amount of Ra226 present in the samples. The concentrations of Ra228 were nearly the same over the whole range of Ra226 concentrations, and the average Ra226/Ra228 ratio increased sharply as the Ra226 content of water increased. The Ra226/Ra228 ratio in the drilled wells varied from 0.3 to 26. Abnormally high Ra226/Ra228 ratios were found in areas with known uranium deposits as well as in several drilled wells at other locations. The abnormally high Ra226/Ra228 ratios present in groundwater suggest that the radioactivity anomaly is caused by uranium deposits and not by common rocks. In samples with a low radioactivity level, the average Ra226/Ra228 ratio was slightly below unity, corresponding to the typical U/Th ratio of granite, the most common kind of rock in the study area. The samples from the rapakivi area proved to be exceptional in that they had a low Ra226/Ra228 ratio, independent of the concentration of Ra226. (Baker-FRC)

FORMS OF THE MIGRATION OF METALLIC IONS IN FRESH WATER,
Akademiya Nauk URSR, Kiev. Inst. Hidrobiologii.
P. N. Linnik, and B. I. Nabivanets.
Hydrobiological Journal, Vol 17, No 1, p 91-92, 1981.

Descriptors: *Ion transport, *Rivers, Manganese, *Dnieper River, Hydrobiology, *Heavy metals, Kinetics, Aquatic life, Chemical composition, Path of pollutants, Pollutant identification, *USSR.

An outline for step by step analysis of surface waters for the content of individual forms of metals has been developed. This outline may be used to determine the following, most general characteristics of the state of metallic ions in fresh water: the distribution of the metal between suspended, colloidal and truly dissolved forms; the concentration of free metallic ions and ions in complexes; the sign of the charge of the metallic ions; the molecular mass of complex or polynuclear compounds; and the degree of oxidation of the metal. The scope of the outline devised has been verifed in a study of the forms of the migration of manganese in the water of the Dnieper River. It has been established that manganese is in a dissolved state in the water of this river as free ions and complex compounds of different molecular mass. Macromolecular manganese complexes are represented mainly by anionic compounds, which are about 85-90% of the total content. Cationic manganese complexes are found in fractions with a molecular mass of about 0.5 to 1.5 thousand. The combining of manganese into complex compounds by the complex-forming substances in the water of the Dnieper is typified by a fairly slow rate. (Baker-FRC)

THE EFFECT OF SULFATE ON ALUMINUM CONCENTRATIONS IN NATURAL WATERS: SOME STABILITY RELATIONS IN THE SYSTEM AL2O3-SO3-H2O AT 298 K,
Geological Survey, Menlo Park, CA.
D. K. Nordstrom.
Geochimica et Cosmochimica Acta, Vol 46, No 4, p 681-692, 1982. 7 Fig, 2 Tab, 93 Ref.

Descriptors: *Aluminum compounds, *Solubility, *Sulfates, Chemical reactions, Chemical precipitation, Gibbsite, Kaolinite, Hydrogen ion concentration, Minerals, Acid rain, Alunogen, Alunite, Jurbanite, Basaluminite, Acid mine drainage, Adsorption, Soil chemistry, Sediments, Clays, Water pollution effects.

In natural waters aluminum concentrations are generally regulated by gibbsite and kaolinite solubilities. However, addition of sulfate by acid precipitation or acid mine drainage can shift solubility control to less soluble minerals. These minerals include alunogen, Al2(SO4)3 x 17H2O; alunite, KAl2(SO4)2(OH)5; jurbanite, Al(SO4)(OH) x 5H2O; and basaluminite, Al4(SO4)(OH)10 x 5H2O. Values for the log of the solubility product constant obtained from the literature or estimated in this work are: alunite, -85.4; basaluminite, -117.7; alunogen, -7.0; and jurbanite, -17.8. The solubility and stability relations among these four minerals were plotted as a function of pH and sulfate activity at 298 K. Within the range of most natural waters (pH 0 to 13 and log of sulfate activity, -6 to 1) alunogen is unstable, jurbanite is stable from pH o to 5, alunite is stable from pH 3 to 7, and gibbsite, from pH 3 to 8. Basaluminite is metastable for all values of pH and sulfate activity. These equilibrium calculations predict that sulfate and aluminum can be immoblized in acid waters by precipitation of aluminum hydroxy sulfates, which rather than adsorption may be the cause of sulfate retention in soils and sediments. THE ORIGIN OF HIGH IRON CONCENTRATIONS IN GROUNDWATER FROM THE TRIASSIC AQUIFER IN EAST DEVON,
Institute of Geological Sciences, London (England).
N. R. G. Walton.
Journal of the Institution of Water Engineers and Scientists, Vol 36, No 1, p 63-77, 1982. 3 Fig, 3 Tab, 20 Ref.

Descriptors: *Iron, *Geochemistry, *Water quality, Chemical composition, Sherwood Sandstone,

Otter Sandstone, Budleigh Salterton Pebble Beds, Aquifers, Groundwater, Wells, Acid water.

Exploratory drilling for groundwater resources in the Sherwood Sandstone aquifer in eastern Devon, England, revealed water of anomalously high iron concentration. Total Fe concentrations were 9800, 3900, and 1400 mg per liter in the three highest-level samples and 4-230 mg per liter in the remaining 17 samples. Ferrous iron levels were 0.01-3.50 mg per liter. This was a result of interdependence between two formations. The upper formation, Otter Sandstone, acts as a confining stratum for the Budleigh Salterton Pebble Beds, promoting reducing conditions in the Pebble Beds and mobilizing iron in the ferrous form. The tendency toward natural upward flow from the Pebble Beds to the Otter formation and the acid nature of the Pebble Beds water (pH 5.0) cause the high iron levels in the mixed groundwater. To minimize Fe content in wells drilled in this region the lower Pebble Beds formation should not be penetrated or approached closely in drilling a well, except in the region within 1.5 km of the outcrop. Conditions such as faults, permeable strata, and connections between the two formations will promote leakage of Pebble Beds water into Otter Sandstone wells. Proper positioning of the well screen and careful managing of pumping regime can also help avoid excessive Fe concentrations in abstracted water. (Cassar-FRC)

INFLUENCE OF DISSOLVED ORGANIC MATERIALS ON TURBID WATER OPTICAL PROPERTIES AND REMOTE-SENSING REFLECTANCE,
National Aerounautics and Space Administration, Hampton, VA. Langley Research Center.
W. G. Witte, C. H. Whitlock, R. C. Harriss, J. W. Usry, and L. R. Poole.
Jounral of Geophysical Research, Vol 87, No c1, p 441-446, January 10, 1982. 11 Fig, 2 Tab, 18 Ref.

Descriptors: *Dissolved solids, *Remote sensing, Turbidity, Measuring instruments, Water quality, Physical properties, Rivers, Georgia, Humic acids.

The purpose of this study was to assess quantitatively the influence of dissolved organic matter on turbid water optical properties and remote sensing reflectance over a range of concentrations typical of inland and coastal waters. Both field measurements and laboratory results were studied. Field measurements were taken of upwelled water volume reflectance on five of the major rivers of Georgia. Results implied that dissolved organic matter has the effect of reducing the inherent reflectance of turbid water mixtures, but a firm conclusion to that effect could not be made because of possible variations in uncontrolled variables such as solar elevation angle, atmospheric haze, chlorophyll, sediment mineralogy, iron content, and particulate organic carbon. Controlled lab tests were conducted in an attempt to isolate the optical effects of dissolved humic acids. The laboratory measurements showed nonlinear degradation in reflectance signals with changing dissolved organic carbon at visible and some near-infrared wavelengths, with degradation gradients greatest for dissolved organic carbon concentrations less than 3 mg/liter. Theoretical analysis, using a model relating upwelled reflectance to backscattering and absorption parameters, confirmed the nonlinear nature of the experimental results. (Baker-FRC)
W82-05869

EVALUATION OF THE RATE OF UPTAKE OF NITROGEN DIOXIDE BY ATMOSPHERIC AND SURFACE LIQUID WATER,
Brookhaven National Lab., Upton, NY. Dept. of Energy and Environment.
Y.-N. Lee, and S. E. Schwartz.
Journal of Geophysical Research, Vol 86, No C12, p11971-11983, December 20, 1981. 2 Fig, 2 Tab, 78 Ref.

Descriptors: *Nitrogen dioxide, *Surface water, Chemical reactions, Absorption, Sulfur, Water pollution sources, Solubility, Chemistry of precipitation, Acid rain, Catalysts, Clouds.

The rate of uptake of nitrogen dioxide by liquid water was shown to be unaffected by oxygen at 0.2 atm pressure. Therefore, the rate constant and Henry's law solubility constant of nitrogen dioxide previously obtained may be used to evaluate the rates of aqueous phase reactions of nitrogen dioxide in the ambient atmosphere. Reactions are quite slow at representative atmospheric partial pressures and cloud liquid water content. The characteristic times range upward from 1000 to 10000 hours at 0.1 microatm, increasing with decreasing partial pressures of the gases. Direct acidification of cloud liquid water is also unimportant. Catalytic enhancement is potentially important for catalyst concentrations of the order of 0.1 microatm, assuming sufficiently fast rate constants. Iron-catalyzed reaction in particular was unimportant. Reaction of nitrogen dioxide with dissolved sulfur is potentially important, based on an assumed upper limit rate constant of 0.25 micromolar per sec. Deposition of nitrogen dioxide to surfaces of oceans or lakes is shown to be controlled by aqueous phase mass transport and/or reaction and is much slower than heretofore assumed. (Baker-FRC)

SEDIMENT WATER EXCHANGES OF NUTRIENTS AND OXYGEN ON TIDAL FLATS IN THE EMS-DOLLART ESTUARY,
Nederlands Inst. voor Onderzoek der Zee, Texel. Biological Research Ems-Dollart Estuary.
M. M. Rutgers Van Der Loeff, F. B. Van Es, W. Helder, and R. T. P. De Vries.
Netherlands Journal of Sea Research, Vol 15, No 1, p 113-129, October, 1981. 9 Fig, 2 Tab, 50 Ref.

Descriptors: *Estuaries, *Tidal flats, *Nutrients, *Oxygen uptake, *Light penetration, *Marine sediments, Tidal marshes, Cycling nutrients, Oxygen balance, Silica, Nitrogen, Oxygen, Phosphates, Nitrate, Ammonia, Interstitial water, *Netherlands, Ems-Dollart Estuary.

The relationship between oxygen exchange and nutrient exchange on the tidal flats of the Ems-Dollart Estuary of the Netherlands was examined by bell jar experiments in an attempt to qualitatively evaluate the effect of these exchanges on the nutrient budgets of the estuary. At two sampling stations, the exchange of ammonia and silica was correlated with oxygen exchange and light conditions. Throughout the entire year, the Heringsplaat in the Dollart River was a sink for nitrate, ammonia, and silica in both light and dark periods even during periods of net oxygen consumption. The other two sampling sites showed different patterns due to a longer emersion period at the Heringsplaat and a greater supply of nutrients. In general, phosphate exchange was low, except at the Heringsplaat in June, where a release of 1 mmol/sq m/day was recorded. In the Dollard, a net release of silica in late summer was attributed to the dissolution of suspended material in the water phase. Inorganic nitrogen supplies may become depleted at the sediment surface during emersion, thereby restricting the growth of diatoms. (Geiger-FRC)

Netherlands Journal of Sea Research, Vol 15, No 1, p 88-99, October, 1981. 3 Fig, 2 Tab, 35 Ref.

Descriptors: *Estuaries, *Decomposing organic matter, *Fluorescence, Water analysis, Mixing, Salinity, Tracers, Environmental tracers, Organic matter, Distribution, Decomposition, Temperature, Hydrogen ion concentration, Phytoplankton, *Netherlands, Ems-Dollart Estuary.

From October 1978 to October 1980, the fluorescence was measured in the Ems-Dollart Estuary to characterize the mixing patterns of the waters and identify the types of matter connected with the fluorescence. It was concluded that the fluorescence originates from fluvial sources and behaves conservatively from the linearity of the inverse relation between fluorescence and salinity. At high salinity, there was an increase in fluorescence during the summer months in the outer portions of the estuary. These increases could be due to accumulated fluorescent matter due to slower decomposition at high salinities, in situ formation of fluorescent substances from the degradation of phytoplankton changes in water temperature or pH causing a disturbance in the equilibrium between dissolved particulate and dissolved fluorescent substances, or a combination of these. Ultrafiltration was performed during five surveys between February and August of 1980 to determine the polymeric character of the fluorescent matter. A fraction with molecular weight < 500 showed a high contribution to the total fluorescence for all dates. It was deemed possible for the measure of aggregation of fluorescent matter to fluctuate during transport through the estuary. (Geiger-FRC)

SEDIMENT TRANSPORT AND SHOALING IN ESTUARINE AND OTHER SHALLOW-WATER AREAS,
Old Dominion Univ., Norfolk, VA. Dept. of Oceanography.
J. C. Ludwick, and C. E. Grosch.
Ocean Science and Engineering, Vol 6, No 2, p 163-194, 1981. 88 Ref.

Descriptors: *Sediment transport, *Estuaries, *Shoals, Shallow water, Sedimentation, *Sediment distribution, Estuarine environment, Environment, Bed load, Sediment load.

This paper discusses four sediment transport formulations, with the aim of emphasizing the need to understand mechanics of the problem in spite of the present incompleteness of the solutions. Knowledge of sediment transport mechanics, particularly the sediment transport continuity equation, can increase insight into erosion and deposition. Specific discussion is offered on the Shields Bed Load transport equation, which pertains to a sediment bed on which the surface grains are in strong motion and hence no longer form a flat surface, but instead are shaped into scales or bars of low height to length ratio. Also discussed are the Einstein and Einstein-Brown equations for bed load transport, the 1950 Einstein bed load transport function, and the Bagnold 1973 formulation for bed load transport rate. MODELING: HOW AND WHEN TO USE,
Army Engineer Waterways Experiment Station, Vicksburg, MS.
W. H. McAnally, Jr.
Ocean Science and Engineering, Vol 6, No 2, p 149-162, 1981. 12 Ref.

Descriptors: *Model studies, *Estuarine environment, *Sedimentation, *Sediment transport, Cost analysis, Economic aspects.

In order to determine if modeling is an appropriate approach to specific problems, the physical processes contributing to a sedimentation problem must be understood. Potential sources of estuarine sediments include: upland drainage basins; the estuary itself through erosion of banks, bottoms and marshes; the ocean; municipal and industrial wastes; windborne sediment; and organic materials. Different sediments will predominate in different parts of an estuary. Estuarine sedimentation is dependent upon the supply of depositable sediment and flow conditions near the bed. Four primary

LIBRARY U. Of I.- URBANA-CHAMPAIGN

methods are used for studying estuarine sedimentation - field methods, analytical methods, physical modeling and numerical modeling. Numerical modeling is relatively new and employs special computational methods such as iteration and approximation to solve mathematical experssions that do not have closed form solutions. Numerical modeling provides much more detailed results than analytical methods and may be more accurate, but is also more expensive and time consuming. Modeling should be employed when the cost or importance of the problem justifies the time and cost of modeling and the dominant processes involved are susceptible to modeling. Most estuarine construction projects are either very expensive or possess the potential for expensive side effects. (Baker-FRC)

Descriptors: *Sedimentation, *Zooplankton, *Phytoplankton, *Estuarine environment, Boddens, Bays, Salinity, Productivity, Detritus, *Baltic Sea, Coastal waters, Lagoons.

Complex studies on the hydrographic and biological regime have been underway in the area of the shallow bays (bodden) to the south of the Darss and Zingst peninsulas since 1969. The relationships between the water body and the sediment are especially close in shallow water areas such as those studied. In the current investigation, quantitative and qualitative studies were performed on the sedimentation of the phytoplankton and zooplankton in the western portion of the Bodstedter Bodden. The phytoplankton sedimentation rate varies with the species, but in general the groups most numerous in the water are also most common in the sediment. The two peaks observed in the phytoplankton growth in the water were reflected without time lag in the detritus (August 6 and 14, 1975). The Bacillariophyceae had the highest sedimentation rate. The sedimentation rate of the Chlorophyceae was greater than that of the Cyanophyceae, but the absolute numbers of the former were smaller. Very high zooplankton abundances were found, averaging 27,000 individuals/liter. Rotatoria represented the most common species. The organisms found were freshwater species. Interpretation due to the sporadic occurrences of some species. The small numbers of sedimenting zooplankton were balanced by their greater biomass, and relative to their occurrence in the water, larger numbers of zooplankters sedimented each day. A total mean plankton sedimentation rate accounting for 16% of the deposition volume was found. (Carroll-FRC)

Descriptors: *Sedimentation, *Estuarine environment, *Productivity, Chemical oxygen demand, Organic matter, Boddens, *Baltic Sea, Bays, Coastal waters, Lagoons, Shallow water, *Energy balance, Phosphorus, Iron.

The boddens to the south of the Darss and Zingst peninsulas are a system of communicating water bodies connected with the Baltic Sea and presenting estuarine conditions, with salinities decreasing with distance from the Baltic. The water is very shallow (average depth 1.7 m, maximum 12 m); wind-induced turbulence can constantly rearrange large areas of sediment surface, making sedimentation studies very difficult. Studies were conducted at a relatively sheltered site when the salinity was relatively high (0.5%) and the water was warm (average for August 1975, 18-19 C). Two types of sediment traps were used: plastic funnels and settling tubes; best results were achieved with the funnels. An average sedimentation rate of 1316 ml/sq m was measured for July/August 1975, with a dry matter content of 16.4 g/sq m. The organic matter content (loss on ignition) was 64.4% on August 1, and the COD was 786 mg 02/mg dry matter. The iron/phosphorus ratio averaged around 2.5 in freshly sedimented material. An estimation of the energy content of the sediment suggested that about 1% of the solar irradiation is initially stored in the sediment. The information obtained will be used for formulating a mathematical model of the ecosystem. (Carroll-FRC)

DISTRIBUTION OF METHANOGENIC AND SULFATE-REDUCING BACTERIA IN NEARSHORE MARINE SEDIMENTS,
Connecticut Univ., Noank.
M. E. Hines, and J. D. Buck.
Applied and Environmental Microbiology, Vol 43, No 2, p 447-453, February, 1982. 2 Fig, 1 Tab, 31 Ref.

Descriptors: *Bacteria, *Marine sediments, Sedimentation, Sediments, Estuarine environment, Sulfates, Population dynamics, Methanosarcina, *Long Island Sound.

Populations of both methanogenic and sulfate-reducing bacteria were investigated in various sediments of eastern Long Island Sound and contiguous waters to determine whether their distribution agreed with previous hypotheses. The findings suggested that the distribution of abundant methanogenic and sulfate-reducing bacteria were mutally exclusive in these marine sediments. Three distributional patterns were noted. Four sites exhibited methanogenic and sulfate-reducing populations which were restricted to the upper 10 to 20 cm, with a predominance of sulfate reducers. Three sites in western Long Island Sound exhibited a methanogenic population most abundant in sediments deeper than those occupied by sulfate reducers. At one site which was influenced by fresh groundwater, methanogens and sulfate reducers were numerous within the same depths, however, the number of sulfate reducers varied vertically and temporally with sulfate concentrations, Methanogenic enrichments yielded all genera of methanogens except Methanosarcina, with the methanobacteria predominating. Descriptors: *Bdellovibrios, *Bacteria, *Seasonal variation, Vibrios, Rivers, *Patuxent River, *Chesapeake Bay, Marine bacteria, Predators, Estuaries.

Marine bdellovibrios, bacterial predators of susceptible gram-negative bacilli, were cultured from samples taken monthly from June 1979 to June 1980 at the end, middle, and shoreline of a pier at Solomon's Island, Maryland in the mouth of the Patuxent River, Chesapeake Bay. The number of bdellovibrios was highest in April-June and decreased to a low in January-March. With one exception the shoreline site had higher counts than the middle and end of the pier. The number of bdellovibrios was also significantly correlated with water temperature. In July-September, the mean water temperature was 26 C, slightly above the 23-25 C temperature for optimum growth. Bdellovibrios (in plaque-forming units per 10 ml) recovered at the shoreline site were: 178.8 + or - 205.5 in April-June, 158.7 + or - 145.8 in July-September, 91.8 + or - 16.0 in October-December, and 7.2 + or - 6.7 in January-March. A NEW METHOD OF CUBATURE USING SPLINE FUNCTIONS,
Louvain Univ. (Belgium). Applied Mathematics Div.
P. Dierckx, E. Smets, R. Piessens, and M. Temmerman.
Deutsche Hydrographische Zeitschrift, Vol 34, No 2, p 61-69, 1981. 7 fig, 4 Tab, 13 Ref.

Descriptors: *Tidal basins, *Discharge measurements, *Water level fluctuations, Tidal rivers, Cubature calculations, Spline approximations, *Schelde Basin, Estuaries, River basins, Stream discharge, Flood discharge, Ebb discharge, Netherlands, Belgium.

This paper presents a new method for cubature calculations to obatin a value for river discharge which is more accurate than those obtained by measurement of current velocities. The method uses measurements of water level variations in a limited number of cross sections along with a knowledge of the geometry and upstream discharge. Spline approximations are constructed for the discharge variations in several rivers in a given tidal basin. This smooths out the effects of measuring errors. The approximations may be evaluated for any location or time in the total region. Ebb and flood volumes can be easily evaluated. The Schelde tidal basin, the Netherlands and Belgium, is used to illustrate the calcualtion procedure. (Cassar-FRC)

THE ECOLOGY OF PLANKTON FAUNA IN SALINE RIVER POOLS,
Western Australia Inst. of Tech., Perth. Dept. of Biology.
R. J. Rippingale.
Hydrobiologia, Vol 82, p 223-232, 1981. 5 Fig, 2 Tab, 8 Ref.

Descriptors: *Saline water, *Plankton, *Estuaries, Fauna, Benthic fauna, Rivers, Ponds, River pools, Salinity, *Swan-Avon River system, *Australia.

The occurrence of a planktonic copepod typical of estuaries in pools of the Swan-Avon river system is investigated. Plankton samples were taken from a number of pools during 1972 and 1979. Any discussion of the mechanism for the initial recruitment of an estuarine fauna into saline river pools during this century can only be speculative. Upstream penetration could not have occurred due to rapids and periods at which the river bed is dry. One transport mechanism which is possible would in-

volve the use of waterfowl. However, recriutment must be a continual event, as the Sulcanus conflictus could not survive winter floods in this area. The fact that dense populations of adult S. conflictus frequently dominate the saline pools is explained by their omnivorous feeding habit. S. conflictus exploits phytoplankton in the estuaries and saline river. Thus with the ability to survive both as a filter feeder and a predator, and with significant tolerance to low environmental salinities, S. conflictus was able to extend its range into the saline pools of the Avon River when this habitat became available during historical times through increase in groundwater salinities. A SYSTEM FOR MEASURING METHANE FLUXES FROM INLAND AND COASTAL WETLAND ENVIRONMENTS,
National Aeronautics and Space Administration, Hampton, VA. Langley Research Center.
D. I. Sebacher, and R. C. Harriss.
Journal of Environmental Quality, Vol 11, No 1, p 34-37, January-March, 1982. 3 Fig, 30 Ref.

Descriptors: *Wetland, *Methane, Measuring instruments, *Air-water interfaces, Interfaces, Fluctuations, Monitoring, Bayous, Bogs, Fens, Marshes, Muskeg, Swamps, *Tide lands, Estuaries.

A simple monitoring system for measuring methane fluxes at the water-air interface in wetland environments has been developed and field tested. The system permits precise detection of methane emission rates as low as .0001 g methane per square meter per day in 5 minutes or less. Systematic studies on the importance of methane in the carbon budget of flooded agricultural soils, wetland waste management sites, salt marshes and inland wetlands may be possible. The method employs a partitioned chamber placed over the water surface where the air velocity along the surface can be controlled. Emission rates of gas across an air-water interface are controlled by shear stress of winds in the overlying gas. Therefore the objective of the present studies was to develop a relatively simple field system with the capability of quantitatively controlling air velocity over water surface within the chamber sampling area. The technique has the important advantage of including a continuous monitoring system so that data can be observed on site. Measurements obtained in a coastal wetland creek demonstrated that the methane flux passing through a water-atmosphere interface can be quantified as a function of air velocity over the water surface. COMPOSITION OF ESTUARINE COLLOIDAL MATERIAL: MAJOR AND TRACE ELEMENTS,
Maryland Univ., College Park. Dept. of Chemistry.
A. C. Sigleo, and G. R. Helz.
Geochemical et Cosmochimica Acta, Vol 45, No 12, p 2501-2509, December, 1981. 6 Fig, 4 Tab, 38 Ref.

Descriptors: *Chemical composition, *Colloidals, *Estuaries, Trace levels, Seasonal variation, Aluminum carbon, *Patuxent River, *Maryland.

Instrumental neutron activation analysis was used to analyze colloidal sized material from the Patuxent River estuary, in Maryland, for more than 30 elements, Data on samples taken from five stations, ranging in salinity from 0.04 grams per kiogram (g/kg) to 12 g/kg, in February and June indicate that the winter colloidal material is dominated upstream by poorly crystallized clay minerals and iron oxide, but that it consists primarily of carbonaceous material at salinities over 10 g/kg. During the winter, colloidal material decreases non-conservatively seaward from 29 to 0.6 milligram per liter. The summer colloidal material was found to be carbon-rich throughout the estuary and the amount of colloidal material in the upper water column did not change significantly with increasing salinity. Trace elements which covary with aluminum, including cesium, hafnium, rubidium, scandium, thorium, vanadium, and the REE, are probably associated with the clay component of the colloidal material. Other elements, including selenium, arsenic, barium, uranium, and zinc, were considerably enriched relative to aluminum and may covary with the organic component. These findings suggest that while the freshwater summer colloidal material is derived primary from estuarine biological processes, the winter colloidal system is a product of continental weathering processes. A NEW METHOD OF CUBATURE USING SPLINE FUNCTIONS,
Louvain Univ. (Belgium). Applied Mathematics Div.
P. Dierckx, E. Smets, R. Piessens, and M. Temmerman.
Deutsche Hydrographische Zeitschrfit, Vol 34, No 2, pp 61-79, August, 1981. 4 Tab, 7 Fig, 13 Ref.

Descriptors: *Discharge, *Floods, *Tides, *Mathematical studies, *Cross-sections, Tidal floods, Time series analysis, Basins, Flood basins, Equations, Simulation analysis, Seasonal variation, Hydrographs, Velocity, Flow discharge, Flood data, *Cubature, Water level fluctuations.

A new method for cubature calculations is presented. The cubature requires measured water-level variations in a limited number of cross-sections and knowledge of the geometry and of the upstream discharge as a boundary condition. By numerical integration of the continuity equation, spline approximations are constructed for the discharge variations in the different rivers of a given tidal basin. In that way measuring faults and their efects are smoothed out. Once the approximations are obtained, they can be evaluated in a quick and accurate way for any location in the tidal region and at any time. Derived quantities as ebb- and flood-volumes can be evaluated likewise, in a very simple procedure. A computer program based on this method is described. Some results from the basin of the Schelde estuary in the Netherlands and Belgium are presented; they confirm the validity of the method. (Titus-FRC)

THE TIDAL STREAM IN THE GERMAN BIGHT,
Deutsches Hydrographisches Inst., Hamburg (Germany, F.R.).
C. Brockmann, W. Lange, E. Mittelstaedt, and K. C. Soetje.
Deutsche Hydrographische Zeitschrift, Vol 34, No 2, pp 56-60, August, 1981. 1 Tab, 4 Ref.

Descriptors: *Bights, *Bays, *Estuaries, *Currents, *Time series analysis, Sounds, Estuaries, Hydrologic data, Water depth, Mathematical models, *German Bight, Tidal effects, Tidal currents.

A numerical model of the German Bight is presented and current measurements are compared with the model results. The model is three-dimensional with four layers in the German Bight, and two-dimensional in the coupled North Sea. Tidal stream vectors resulting from the model are compared with data obtained over a twenty year period for hourly intervals in spring high water conditions. Spring conditions were chosen for simulation because during this time the diurnal inequalities of the tides are minimum. The model currents compare well with the observed tidal streams in areas with water depths greater than 10 meters. In shallower regions local topographic differences influence currents. (Titus-FRC)

INITIAL COLONIZATION OF ARTIFICIAL SUBSTRATE: COMMUNITY DEVELOPMENT AND STRUCTURE STUDIED BY SCANNING ELECTRON MICROSCOPY,
Laval Univ., Quebec. Dept. de Biologie.
C. Hudon, and E. Bourget.
Canadian Journal of Fisheries and Aquatic Sciences, Vol 38, No 11, p 1371-1384, November, 1981. 7 Fig, 7 Tab, 49 Ref.

Descriptors: *Substrates, *Population dynamics, *Estuaries, Bacteria, Diatoms, Electron microscopy, Intertidal areas, Canada, *St. Lawrence Estuary.

A 90 kilometer section of the south shore of the lower St. Lawrence Estuary, which is influenced by strong semidiurnal tides, was used for a quantitive study of the community development and biological interactions occurring in a slow-growing, low-density periphytic assemblage. The initial phases of the subtidal and intertidal community development were observed using scanning electron microscopy on samples from plastic panels immersed monthly in the estuary between May and November 1978. The community structure was significantly influenced by the pattern of immersion and/or periodical emersion. Subtidal panels were rapidly colonized by bacteria, while diatoms settled 2 to 7 weeks later, depending on the season. All dominant species formed well-defined, generally monospecific clumps until mid-September. Clump overlap and increased species interactions occurred with higher cell densities. In the intertidal zone, bacteria settled after 8 to 12 weeks, while the only diatom species able to resist semidiurnal emersion, Achnanthes brevipes, appeared after 20 weeks. Panels emersed only at spring tides (monthly) were rapidly colonized by bacteria, with heavy diatom settlement occurring within 4 weeks. These diatom populations were eliminated or strongly reduced by successive monthly emersions and were replaced by filamentous algae. The various types of communities are compared and the strategic advantages of vertical growth discussed with reference to population density, light availability, and detrital cover. (Carroll-FRC)

R. B. Ambrose, Jr., and S. E. Roesch.
Journal of the Environmental Engineering Division, Proceedings of the American Society of Civil Engineers, Vol 108, No EE1, p 51-71, February, 1982. 5 Fig, 7 Tab, 17 Ref.

Descriptors: *Estuaries, *Model studies, Mathematical models, Estuarine environment, *Delaware Estuary, *Potomac Estuary, Water quality, Sediment transport, Hydrodynamics, Mass transfer, *Tidal effects, Inflow, Rainfall impart, *Stream discharge.

This report evaluates how well the dynamic estuary model (DEM) simulates historical hydrodynamic, mass transport, and water quality data in the Delaware and Potomac Estuaries. The Delaware and Potomac Estuaries are drowned river valleys. Well-defined heads-of-tide are located at the fall line between the piedmont and coastal plain. Freshwater inflow controls the net seaward advection. Wind stress adds a significant stochastic variation. Dredging is required to maintain navigational channels. The Delaware Estuary application of the DEM yielded coefficients of variation between 2% and 10% for the most important hydrodynamic variables, between 13 and 45% for the important transport variables, and between 15 and 41% for the water quality variables. The Potomac Estuary application gave coefficients of variation from 5 to 7% for the hydrodynamics, 5 to 44% for the transport, and 11 to 267% for water quality. The Potomac water quality response falls between 11 and 90%. Correlation coefficients showed the same trends. These statistics reveal the DEM to be basically reliable when operated within the range of conditions for which it is calibrated and tested. Certain limitations should be remembered. The model cannot reliably predict transient or steep concentration gradients with precision exceeding 5 kilometers or three hours. Above these limits the model is limited by the precision of the input data and the nature of the water quality structure implemented. The model should be able to predict relative changes in water quality expected from incremental wastewater management alternatives. (Baker-FRC)

WETLANDS AND DEEPWATER HABITATS: A NEW CLASSIFICATION,
Fish and Wildlife Service, Jamestown, ND. Northern Prairie Wildlife Research Center.
L. M. Cowardin.
Journal of Soil and Water Conservation, Vol 37, No 2, p 83-85, March/April, 1982. 2 Fig, 1 Tab, 15 Ref.

Descriptors: *Wetlands, *Classification, *Habitats, Marshes, Swamps, Vegetation, Hydrophytes, Soil types, Water chemistry, Lakes, Rivers, Estuaries, Marine environment, Aquatic habitats, Deep-water habitats.

A new classification system for wetlands and deep water habitats was developed by the Fish and Wildlife Service starting in 1974 with a national wetlands inventory. The system is hierarchical (system, subsystem, class, subclass). The first level (system) includes marine, estuarine, riverine, lacustrine, and palustrine. These are further divided into subsystems: subtidal and intertidal for marine and estuarine; tidal, lower and upper perennial, and intermittent for riverine; and limnetic and littoral for lacustrine. Classes include some of the following, depending on the subsystem: rock bottom, unconsolidated bottom, aquatic bed, reef, rocky-shore, unconsolidated shore, streambed, emergent wetland, scrub-shrub wetland, forested wetland, and moss-lichen wetland. Classes are defined by form of vegetation or substrate composition. Modifying terms are used with the classes--water regime, water chemistry, soils, and dominance type. Classes are divided into subclasses on the basis of the same attributes used to form classes. An example of the classification of a specific Massachusetts salt marsh is as follows: System: Estuarine; Subsystem: Intertidal; Class: Emergent wetland; Subclass: Intertidal; Subclass: Persistent; Water regime: Regularly flooded: Water chemistry: Mixohaline; Soil: Organic (Sulfihemist); and Dominance type: Spartina alterniflora. Chemical Engineering Progress, Vol 77, No 7, p 72-73, July, 1981. 2 Fig.

Descriptors: *Desalination plants, *Evaporation, *Distillation, *Seawater, Vertical tube evaporation, Vapor compression, Energy, Reverse osmosis, Multistage flash distillation, Heat transfer.

A combined vertical tube evaporation and vapor compression process has been applied to sea water desalination. Since the performance ratio of this process increases almost linearly with the number of effects in the unit, the process has an advantage over multistage flash distillation when energy is at a premium. For a 24-effect process the practical performance ratio of 21 is raised to 42 by passing the boiler steam through a turbine to drive the vapor compressor of the topping effect. The compressor elevates the saturation temperature of the stream so it can be used as heating steam in the same effect. The vapor condensed in the topping effect increases total distillate production by 100% with no increase in heat. This process has been incorporated in a barge-mounted plant capable of producing 5000 cu m of water per day. It also uses partial softening of seawater feed by ion exchange pretreatment. (Cassar-FRC)

RECONNAISSANCE SAMPLINGS AND CHARACTERIZATION OF AQUATIC HUMIC SUBSTANCES AT THE YUMA DESALTING TEST FACILITY, ARIZONA,
Geological Survey, Denver, CO. Water Resources Div.
R. L. Malcolm, R. L. Wershaw, E. M. Thurman, G. R. Aiken, and D. J. Pinckney.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-177965, Price codes: A05 in paper copy, A01 in microfiche. Geological Survey Water-Resources Investigations 81-42, 1981. 79 p, 9 Fig, 31 Tab, 21 Ref.

Descriptors: Fulvic acids, *Reverse osmosis, *Mmbrane processes, Chromatography, Chlorination, Clay minerals, *Desalination, Fouling, Water quality, Chemical analysis, *Arizona, *Yuma Desalting Test Facility.

Smectite clay minerals were found to be the principal compound on the surface of the cellulose-acetate, reverse-osmosis membranes at the Yuma Desalting Test Facility. These clay minerals were not present in the pumped ground water, but were blown into the conveyance canal from adjacent soils. Humic substances from the water and suspended sediments were associated with the clay films on the membrane, but no definitive results concerning their role in fouling were achieved. Microbial fouling is believed to be only a minor aspect of membrane fouling. Chemical and physical changes in humic substances were extensively studied at four points in the water-treatment process. Humic substances accounted for the largest component (over 25 percent) of organic constituents. Humic substances in the canal source water were similar to other aquatic humic substances present in natural waters. During the treatment process, these substances are brominated and decolorized. The effect of these halogenated humic substances on membrane fouling is unclear, but their presence in the reverse-osmosis product water and reverse-osmosis reject brine, along with volatile trihalomethanes, has led to environmental concerns. LOW TEMPERATURE EVAPORATION PLANTS,
Isreal Desalination Engineering Ltd., Tel-Aviv.
D. Hoffman.
Chemical Engineering Progress, Vol 77, No 10, p 59-62, October, 1981. 6 Fig.

Descriptors: *Desalination, *Distillation, *Evaporation, Seawater, Saline water, Temperature, Vapor compression distillation, Scaling, Low temperature operation, Energy, Heat transfer, Wastewater treatment, Corrosion.

Low-temperature plants for seawater distillation have significant advantages over conventional distillation plants. These low-temperature plants commonly operate at 30-55 C with a maximum of 75 C. At these temperatures scale formation from non-acid soluble scalants (magnesium hydroxide and calcium sulfate) and soft acid-soluble calcium carbonate scales is minimized, allowing operation up to 2.5 years without cleaning. In addition, low cost PVC and other plastics may be used. A relatively inexpensive aluminum alloy, superior in heat transfer and corrosion resistance, may be used in place of copper-nickel alloys or steel. Low-temperature vapor compression plants require small feed heat exchangers, little or no insulation, no make-up heat, and permit quick start-up. The same features are applied to multi-effect distillation plants. A 2000 cu m per day plant operates on heat rejected from a 20-MW diesel generator station. The only other energy requirements are 1.5 kW per hour per cu m for process pumping. Concentrators operating at low temperatures can concentrate brackish water by a factor of 300 to 1 (99.5% product recovery) and seawater by a factor of 7 to 1 (85% product recovery). These concentrators produce a distillate of < 5 ppm total dissolved solids and are readily incorporated in zero discharge disposal systems for cooling tower blowdown and other effluents. (Cassar-FRC)

FOAM FRACTIONATION-FLOTATION AS PARTIAL PRETREATMENT FOR REVERSE OSMOSIS,
H. H. Sephton, and D. P. Antonoff.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224676, Price codes: A03 in paper copy, A01 in microfiche. Report, July 1981. 25 p, 6 Fig, 5 Tab, 19 Ref. OWRT S-0075(No 7539(1), 14-34-0001-7539.

Descriptors: *Reverse osmosis, *Foam separation, *Flotation, *Pretreatment of water, *Desalintion, Water quality, Water treatment, Membranes, Turbidity, Coastal waters, Baseline studies, Membrane processes, Seawater, Clarification, Filtration, Saline water, Surface tension, Conductivity, Technology, San Francisco Bay water.

Foam flotation equipment designed, constructed, and tested to assess its utility as a partial pretreatment method on San Francisco Bay water prior to its desalination by reverse osmosis (RO). Test data obtained from a dual-flow facility revealed that foam flotation is effective in reducing feed turbidity, usually by a factor of five (ranging from 3-fold to 10-fold) in terms of national turbidity units. However, due to the poorly-matched single pair of RO units employed, the results could not detect whether feed clarity improvement significantly affected the flux decline or quality of the desalted water produced by RO. The dual-flow facility was comprised of two pretreatment and RO trains and was used for simultaneous comparative testing of conventional cartridge filtration and for the further foam flotation clarification, followed by RO applied to both pretreated feed streams. Surface tension, membrane plugging, and water conductivity were also monitored. The results of this study indicate that further evaluation using well-matched pairs of RO ion-exchange membranes is justified. (Zielinski-MAXIMA)

Two new types of double polyelectrolyte membranes were developed and tested for their application in the desalinization of water by piezodialysis. Membrane I was a fixed (crosslinked) anionic ion-exchanger membrane filled with soluble (linear) cationic polyelectrolyte; membrane II was a fixed cationic ion-exchanger membrane filled with fixed anionic ion-exchanger sites or islands, representing a true mosaic membrane. Both membrane types had their polyelectrolyte island at/near 0.1 micron diameter. Both types showed capability for salt enrichment under applied pressure, while mosaics having polyelectrolyte islands of only 0.003 microns failed to give salt enrichments. Pressure, anion-cation capacity ratios, crosslink density, pore volumes, and salt concentrations were the most important variables affecting salt enrichment. While salt enrichments of these new membranes were less than for latex-polyelectrolyte membranes studied earlier, the new membranes can be easily and reproducibly prepared without mosaic polyelectrolyte loss. Membranes having desalting capacities of 6000-500 ppm NaCl at a production rate of 1 gallon/sq ft/day should be feasible. (Zielinski-MAXIMA)

PARAMETRIC ANALYSIS OF DIRECT-CONTACT (PISTONLESS) WORK EXCHANGER FOR REVERSE OSMOSIS APPLICATIONS,
Hittman Associates, Inc., Columbia, MD.
H. M. Curran.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224825, Price codes: A08 in paper copy, A01 in microfiche. Final Report, HIT-580, August, 1974. Hittman Associates, Inc., Columbia, MD. 69 p, 24 Fig, 13 Tab, 10 Ref, 1 Append. OWRT C-(No 3264)(1), 14-30-3264(1).

Descriptors: *Economic evaluation, *Cost-benefit analysis, *Mechnical engineering, *Desalination, *Reverse osmosis, *Energy transfer, Parametric hydrology, Flow system, Flow discharges, Economic feasibility, Economic justification, Economic efficiency, Economic prediction, Energy loss, Energy dissipation, Cost analysis, Electric power costs, Estimated costs, Operating costs, Flow discharge, Flow rates, Brine disposal, Saline water.

A direct-contact (pistonless) work exchanger concept was analyzed parametrically to determine its economic potential as an alternative to the hydraulic turbine for recovery of flow work from high pressure brine streams discharged by reverse osmosis (RO) plants. The results showed that, for the use of work exchangers to recover energy from RO brine discharges, the break-even unit cost of electric energy increases as the brine volumetric flow rate decreases. Hence, the most cost-effective applications are those with high brine flow rates. The break-even cost at which the exchanger starts to provide a net unit water cost reduction ranges from about $0.004/Kw-hr (for a 1.3 million gallons/day (MGD) RO seawater plant with 1500 psig module inlet pressure, concentration ratio of 2, and brine flow rate of 1000 gallons/minute (gpm), to about $0.058/Kw-hr (for a 0.05 MGD RO brackish water plant with 500 psig inlet pressure, concentration ratio of 5, and brine flow rate of 10 gpm). The results indicate that these exchangers apply best in large seawater RO plants operating at high pressure and low concentration ratio. Energy recovery in cost-effectiveness for such exchangers, however, is only equivalent to hydraulic turbines for flows below 100 gpm, and is less cost-effective above 100 gpm. (Zielinski-MAXIMA)

FABRICATION AND CHARACTERIZATION OF METAL MEMBRANES HAVING PORE CHARGE CONTROL FOR DESALINATION,
Allied Chemical Corp., Idaho. Idaho Chemical Programs-Operations Office.
G. L. Booman.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224890, Price codes: A02 in paper copy, A01 in microfiche. Report, September 1977. 12 p, 1 Tab. 14-01-0001-1291.

Descriptors: *Desalination apparatus, *Desalination, *Membranes, *Pore size, *Water treatment, Saline water, Membrane processes, Membrane filters, Filters, Pores, Water quality, Water quality control, Thin films, Brines, Seawater, Electrodialysis, Electro-osmosis, Electrical potential, Metallurgy.

Research studies assessed the soundness of the basic principle of using charged metal membrane separation for water desalination, and compared the effectiveness of the metal membranes with currently-available membranes. Desalination by charge control of metal membranes was experimentally verified as a sound concept. While only dilute KCl solutions illustrated the desired salt rejection of greater than 99%, extension of this new technique to seawater compositions should be feasible with refinement of the membrane fabrication technique for 100 A (or similar) pore diameters in the electrically-controlled metal layer of the membrane. Fabrication of suitable metal membrane structures made use of microelectronics industry technology, with radio frequency sputter deposition as the primary method for thin film formation. Plasma etching, high temperature diffusion, fission fragment damage track etching, and various chemical etching procedures were used to fabricate appropriate structures. The use of microporous metal membrane structures for desalination would have unique advantages with respect to chemical resistance, cleaning ease, absence of compaction, thermal stability, biological inactivity, dry storage, and direct control of pore geometry for optimizing to specific applications. A U.S. patent (3,794,174; 'Porous Metal Insulator Sandwich Membrane') covering the charged metal membrane desalination concept evolved from this work. (Zielinski-MAXIMA)

OPERATING EXPERIENCES ON A REVERSE OSMOSIS PLANT WHICH CONVERTS SEA WATER INTO BOILER FEED WATER,
I. Vera.
Industrial Water Engineering, Vol 18, No 6, p 22-29, November/December, 1981. 4 Fig, 4 Tab, 2 Ref.

Descriptors: *Desalination, *Reverse osmosis, Membranes, Electric powerplants, Boiler water, Water treatment, Operating costs, Seawater, Venezuela.

The National Electric Company of Venezuela (CADAFE) operates a surface sea water reverse osmosis desalting plant, producing 1.7 mgd as of the end of 1981. The treated water, wiith less than 100 mg per liter total dissolved solids, is used as boiler feed water and potable water. The installation is expensive to operate, $7.63 per 1000 gal vs. $2.30 per 1000 gal for surface water (if it were available). Costs could be reduced further by prolonging the membrane performance and life. This may be attained by optimizing the pretreatment process, both equipment and chemical dosage. Problems encountered in maintaining a low turbidity feed to the membranes have been: large variation in raw water turbidity, accumulation of sediments at the seawater intake, occasional plugging of chemical feed lines, use of polyelectrolyte which had exceeded its shelf life, and improper frequency of filter backwash. Poor membrane performance was evident during early 1980. It was determined that iron corrosion products in the pumping system were fouling the membranes. Replacement of booster pump barrels with stainless steel eliminated fouling and improved membrane performance. (Cassar-FRC)

WATER AND SALT TRANSPORT IN MEMBRANES,
Michigan Technological Univ., Houghton. Dept. of Chemistry and Chemical Engineering.
K. S. Spiegler.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-232026, Price codes: A04 in paper copy, A01 in microfiche. Report, July 1981. 65 p, 20 Fig, 6 Tab, 48 Ref. C-80319-S(8539)(1). 14-34-0001-8539.

Descriptors: *Membrane processes, *Membranes, *Ion transport, *Theoretical analysis, *Desalination, Ion exchange, Ions, Salt rejection, Saline water, Saline-freshwater interfaces, Permeability, Permeability coefficient, Hydraulic conductivity, Electrolytes, Conductivity, Electrical properties, Hydraulic permeability, Experimental design, Waste transport, Experimental data.

Detailed theoretical aspects and experimental studies in membrane transport of water and salt are discussed. Accurate measurements were made of the isothermal transport of ions and water across a synthetic ion-exchange membrane. Conductivity probe-activated automatic feedback mechanism was employed in which electrolyte transport was determined from the amounts of electrolyte and water that needed to be added to and/or withdrawn from the half-cells separated by the membrane in order to keep the solution concentraton constant. Four types of experiments (electric conductivity; hydraulic permeability and streaming potential; electromigration and electroosmosis; and osmosis, dialysis, and membrane potential) were conducted, leading to the determination of eight independent transport coefficients using the developed apparatus. Membrane systems separated by two dilute NaCl solutions in which Ag-AgCl electrodes were immersed, permitted the checking of two reciprocity relations. These two reciprocities were found to hold for a cation-exchange membrane (CEM) studied, with the highest NaCl concentration being 0.5N. Comparing the conductance coefficients obtained with this CEM to those of another membrane indicated that the CEM had higher permeability characteristics. (Zielinski-MAXIMA)

THE ROLE OF DESALTING TCHNOLOGY IN WATER SUPPLY, WASTEWATER REUSE AND INDUSTRIAL APPLICATIONS,
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-236571, Price codes: A13 in paper copy, A01 in microfiche. Compilation of papers presented at four Technology Transfer Workshops, coordinated by the National Water Supply Improvement Association, November, 1981. 272 p, 72 Fig, 39 Tab.. C-80360-T(No 8709)(1),14-34-0001-8709.

Descriptors: *Desalination, *Conferences, *Water supply, *Industrial water, *Technology transfer, *Water supply development, Demineralization, Wastewater renovation, Water reuse, Water use, Technology, Water resources development, Water conveyance, Water requirements, Water conservation, Water demand, Civil engineering.

A compilation of papers presented at four 1978-79 technology transfer workshops on 'The Role of Desalting Technology in Water Supply, Wastewater Reuse and Industrial Applications' is presented. The material covered is focused towards the enhancement of water resources through technological applications of water demineralization. The papers are segregated into three major categories: overview; case histories; Federal and State programs. Participants of the workshops represent a cross-section of the water desalting industry, including engineering consultants, Federal, State, and local water engineers and managers, and representatives of water treatment equipment. As availability of usable water resources decreases and water demand increases, planners must consider greater use of advanced technologies for desalination and wastewater reclamation. Demineralization of brackish ground and domestic wastewater and seawater conversion are existing activity areas that need technological and practical growth. Topics considered include: desalting processes and pretreatment; wastewater reuse and groundwater recharge; reverse osmosis operations; industrial wastewater recovery through vapor compression evaporation; current and future desalting technology; desalination programs of the U.S. Department of Interior's Office of Water Research and Technology; and desalting operations in various localities (Virginia, Arizona, Texas, Colorado, California). FIELD TEST EVALUATION RESEARCH AND DEVELOPMENT AND OPERATION AND MAINTENANCE OF REVERSE OSMOSIS SYSTEMS AND ELECTRODIALYSIS PILOT PLANTS AT ROSWELL TEST FACILITY.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-236696, Price codes: A11 in paper copy, A01 in microfiche. First Annual Report, October, 1980. 212 p, 8 Fig, 92 Tab, 1 Append. OWRT C-(No 8515)(1), 14-34-0001-8515.

Descriptors: *Field tests, *Reverse osmosis, *Electrodialysis, *Pilot plants, *Feedwater treatment, Membrane processes, Test facilities, Pretreatment of water, Water tratment, On-site tests, Sites, Clarified water, Chlorination, Wastewater treatment, Water purification, Wastewater facilities, Microbiological studies, Desalination, Saline water, Brines, Management planning.

The primary objective of this work is to provide field evaluation testing of the reverse osmosis (RO) and electrodialysis (ED) pilot plants at the Roswell test facility (RTF). This report describes the blend systems, pretreatment systems, and pilot plants, and provides detailed information and test data on the performance of the pretreatment systems and pilot plants. Results of on-going research and development work on microbiological determination and control and details of the mechanical maintenance program are included. Four separate pretreatment and blend systems (a chlorinated and a nonchlorinated feedwater blend system, and two simulated feedwaters) were assessed at the RTF during the past year. In addition, activities were conducted in the operation and maintenance of 14 specific tests concerning RO systems, subsystems, test loops, and the ED reversal pilot plant. These tests included: long-term high-recovery performance evaluation with the RO stage using softened RO brine feedwater and use of concentrated brines for softener regeneration; independent evaluation of membrane performance using a simulated feedwater; evaluation of feedwater containing about 3000 ppm total dissolved solids with/without iodine; tests with/without chlorine; and tests on bacteriological effects. Detailed chemical and physical analysis results on the feedwaters and products are provided. (Zielinski-MAXIMA)

FURTHER RESULTS ON THE PERFORMACE OF PRESENT-DAY OSMOTIC MEMBRANES IN VARIOUS OSMOTIC REGIONS,
InterTechnology/Solar Corp., Warrenton, VA.
G. D. Mehta.
Journal of Membrane Sciences, Vol 10, No 1, p 3-19, 1982. 3 Fig, 7 Tab, 8 Ref.

Descriptors: *Osmosis, *Membranes, Wastewater treatment, *Reverse osmosis, *Membrane processes, Pressure retarded osmosis, Brines, Electric power generation, Saline water.

The performaces of osmotic membranes from several manufacturers were evaluated in osmosis, reverse osmosis (RO), and pressure retarded osmosis (PRO). Flat sheet, spiral-wound minimodules and hollow fiber minipermeators were tested for the purpose of concentrating brine in a salinity power system. Fourteen flat sheet membranes had a 1.2 to 3.0 times lower water permeation coefficient in osmosis than in RO. At higher osmotic pressures and with osmotic pressure on the porous substructure side, the water permeation coefficient in osmosis decreased. There was no permanent damage to the membrane. The UOP 4-port spiral-wound RO minimodule made of cellulose acetate was usable in PRO. However, performance was one order of magnitude less than required for economical power generation in a salinity gradient system. Water permeation coefficients (in cu m per sq m per day per atmosphere) were 0.015 for RO and 0.002 for PRO at lower pressures and 0 to 0.001 for PRO at higher pressures. The DuPont Permasep B-9 RO hollow fibers using potassium alum as the solute at 50-60 C in PRO had water permeation coefficients of 0.003, only 18% of that in RO with NaCl at the same temperatures. Since most osmotic membranes are manufactured for RO, it will be necessary to improve the performance of membranes for use in PRO. (Cassar-FRC)

SEAWATER RO HEADS JAPAN'S WATER REUSE RESEARCH.
World Water, Vol 5, No 3, p 29, 31-32, March, 1982. 4 Fig, 2 Tab.

Descriptors: *Water reuse, *Reverse osmosis, *Desalination, Water conservation, Wastewater treatment, Seawater, Industrial water, Wastewater renovation, *Japan, Membranes, Advanced wastewater treatment, Sludge treatment, Reclaimed water.

The Water Reuse Promotion Center (WRPC) was established in Japan in 1973 to promote desalination technology in that country and abroad. As of January 1981 reverse osmosis accounted for 56.4% of installations, electrodialysis for 23.9%, and distillation for 19.7%. Reverse osmosis research and full-scale operations are active in Japan. In addition, several companies and cities remove salts from municipal sewage effluents to allow their reuse as industrial water. In Mitsubishi's 60-story building, a maximum of 1700 cu m per day of building wastewater is automatically treated for use in toilet flushing. The WRPC is also active in research involving wastewater treatment and sludge treatment and in data collection. (Cassar-FRC)

RICE REIGNS SUPREME AS INDONESIA BUILDS UP THE SAWAHS,
World Water, Vol 5, No 2, p 22-23, February 1982. 2 Fig.

Descriptors: *Irrigation, *Water demand, Farming, Rice, Water supply, Water resources development, Indonesia, Java.

Improved and increased irrigation which has directed water onto every available strip of fertile land, particularly in Java, may make Indonesia self-sufficient in rice supply by the early 1980s. The Kali Progo project in the special province of Jogjakarta is typical of the large scale irrigation schemes being implemented. Population in the project area is 1,200/square km, and there is an urgent need to increase cropping capacity to enable farmers to live. To obtain optimum water flow the system required complete rehabilitation of canals, Construction of volcanic debris check dams and flood diversion channels, remodeling of major intakes, and reconstruction of a number of tributary weirs. The project stretches across a 30 km wide swathe of land containing a sawah area of 103,000 ha, fed by two main canals, the Kalibawang and the Mataram. (Baker-FRC)

CAN HARD-ROCK WELLS SOLVE AFRICA'S IRRIGATION PROBLEM,
D. Gear.
World Water, Vol 5, No 2, p 33-35, 37, February, 1982. 2 Fig.

Descriptors: *Water resources development, *Wells, Water supply, Drinking water, Africa, Irrigation, Water demand.

In African countries, hard rocks cannot usually be exploited economically for crop irrigation by tubewells due to the fact that their yield is too low to help solve water problems. Surface water irrigation is restricted to infrequent local combinations of favorable circumstances. Groundwater, however, can be economically exploited by the use of the most appropriate package of techniques. Crop irrigation using hard rock groundwaters would ideally be performed in separate family operated units, each averaging about one hectare. The shape, dimensions and orientation of the traditional Indian storage well, under the right conditions, enable it to draw upon a much larger volume of slowly permeable rock than does a tubewell, and allows a greater chance of intersecting a number of the more permeable collecting zones within the rock. Another advantage of the Indian storage well is that beyond a certain number of people served, it will usually provide drinking water at a lower cost than tubewells. A variation of the Persian wheel powered by draught animals, might be the most suitable water drawing device. Basin irrigation would probably be used, it is still a good method for unsophisticated conditions, but not the only one. Associated catchment, farm, land-use and water conservation practices are needed for a variety of reasons, including the extension of the period of water availability during adverse climatic conditions and the reduction of soil and timber fuel losses. THE APPLICABILITY OF LARGE-DIAMETER, SHALLOW WELLS TO A COASTAL PLAIN HYDROGEOLOGIC ENVIRONMENT, GEORGIA,
Georgia Southwestern Coll., Americus. Dept. of Geology and Physics.
B. F. Beck.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-236621, Price codes: A03 in paper copy, A01 in microfiche. Report ERC 03-81, November, 1981. 37 p, 13 Fig, 4 Tab, 20 Ref. OWRT A-085-GA(1).

Descriptors: *Shallow wells, *Irrigation wells, *Coastal plains, *Stratigraphy, *Hydrologic as-

pects, Well water, Drilling, Water supply development, Sediments, Coastal aquifers, Hydraulic permeability, Theoretical analysis, field tests, On-site tests, Groundwater, Water quality, Economic aspects, Hydrologic system.

Research was conducted to determine the success of large-diameter shallow wells based on field evaluation of currently-used irrigation pits and a detailed examination of the area stratigraphy. Such wells may prove economically advantageous over deeper wells in the Georgia coastal plains. It was found that shallow Pleistocene coastal plain sediments form a series of alternating bands of lagoonal and barrier island facies deposits laid down by a prograding shoreline, and that the two facies have distinctly different hydrologic characteristics and cannot be treated as a single shallow aquifer. The Clayey lagoonal sediments are impermeable for practical use; the sandy barrier island sediments are highly permeable. Narrow bands of the island sediments are good aquifers. Field tests of two irrigation pits and theoretical predictions indicate that large-diameter shallow wells (irrigation pits) should provide sustained yields of at least 4 up to 20 gallons/minute in older Miocene sediments at the surface inland of the Pleistocene shoreline complex, while island sediments should yield over 100,000 gallons/day. Water quality of the shallow sediments is good to excellent, with shallow wells having total dissolved solids of 100 ppm or less and undetectable bacterial contamination. Further, these wells may cost only 15% that of deeper sand wells or deep wells. (Zielinski-MAXIMA)

SOLUBLE MINERAL CONTENT IN SURFICIAL ALLUVIUM AND ASSOCIATED MANCOS SHALE,
Ben-Gurion Univ. of the Negev, Beer-Sheba (Israel). Dept. of Geography.
J. B. Laronne, and S. A. Schumm.
Water Resources Bulletin, Vol 18, No 1, p 27-35, February, 1982. 8 Fig, 3 Tab, 22 Ref. OWRT B-121-COLO.

Descriptors: Solute, *Alluvium, *Shales, *Minerals, *Salts, River basins, Sedimentation, *Salinity, *Upper Colorado River, Water pollution sources.

Most arid and semiarid regions experience problems resulting from high salt content in soils and from high solute concentrations in runoff. The rate of salt pickup under varying hydrologic conditions depends on net dissolution and sediment removal rates and on soluble mineral content and its spatial and temporal variations. The Mancos Shale terrain is a source of considerable solute contribution to the Colorado River. The spatial variability of soluble mineral content in weathered Mancos Shale and its associated alluvium was studied in an effort to understand the mechanism of salt production and to determine the source of salinity. Soluble mineral content was found to be highly variable in the alluvium and in associated surficial Mancos Shale. However, it was possible to identify lithomorphological units based on the soluble mineral content. Study results show that crusts are leached in deep alluvial fills, and that they have somewhat lower soluble mineral contents than underlying Mancos Shale on hillslopes. The crusts were found to be saline, sometimes efflorescent, in shale bedrock channels or where channels abut against the shale. Soluble mineral content increases in alluvium with decrease in depth of alluvial fill, does not vary significantly with depth in deep alluvial fills, and increases with depth in shallow fills. Soluble mineral content trends identified by this study can be used in the development of mathematical models and land management programs in areas of the Colorado River basin experiencing salinity problems. HOW PROPER PROSPECTING IMPROVES THE ODDS,
International Reference Center for the Community Water Supply, the Hague (Netherlands).
E. Hofkes, and L. Terwey.
World Water, Vol 5, No 3, p 41-43, March, 1982. 3 Fig.

Descriptors: *Groundwater mining, *Measuring instruments, *Resistivity, Electrical well logging, Groundwater availability, Groundwater movement, Groundwater potential, Well logs, Seismic refraction, Remote sensing, Tracers, Radioactive tracers.

Proper groundwater prospecting is important in providing water supplies in developing regions. After the objective is defined (local or regional supply), a systematic approach is used. First, all available hydrogeological data are studied. Then the study area should be surveyed, preferably toward the end of the dry season. Among the surface geophysical methods electrical resistivity and seismic refraction are suitable for prospecting in shallow formation. Equipment is readily available. Geophysical well logging provides data on the physical properties and characteristics of the formations, water quality, and proper well construction. Well logging may involve measurements of electric resistivity, spontaneous potential, and natural gamma radiation. Aerial methods are photography, multispectral and thermal infrared scanning, and side-looking radar. Radioisotopes (deuterium, 018, tritium, and C14) are used as tracers to study groundwater movement, residence time, recharging, and location. (Cassar-FRC)

FOREST MANAGEMENT FOR INCREASED WATER YIELD--HOW USEFUL IN SOUTHERN ALBERTA,
C. R. Neill.
Canadian Water Resources Journal, Vol 5, No 1, p 56-75, 1980. 4 Fig, 1 Tab, 16 Ref.

Descriptors: *Forest management, *Vegetation effects, *Water yield improvement, Small watersheds, Clearcutting, Alberta, Oldman River, Forest watersheds, Snowmelt, Chinook, Colorado, Land management, Flow augmentation, Watershed management, River basins, Seasonal variation.

Reducing forest cover to increase water yield in the Oldman River Basin, Alberta, would produce questionable benefits and possibly adverse effects on flow regulation and water quality. Data from international research on small basins indicate that clearcutting increases water yield from 5 to 50%, highest in warm humid regions. Thinning or selective cutting produces negligible effects. Yield gradually decreases with vegetation reestablishment and reforestation. In some regions such as Colorado the increased yield occurs almost entirely in the snowmelt period. It is unreliable to extrapolate results from one region to an untested region. Results from large basins and from Russia are less conclusive and sometimes contradictory. Although clearcutting in Colorado increased water yield by 18-31%, results from Alberta experiences in clearcutting were inconclusive. Estimates of water yield increases by manipulating 1300 sq km of forest at Lethbridge are 2% of natural average flow averaged over the life of the timber cycle and nonexistent during dry year sequences. COMPARISON OF COLIPHAGE AAD BACTERIAL AEROSOLS AT A WASTEWATER SPRAY IRRIGATION SITE,
Army Medical Bioengineering Research and Development Lab., Fort Detrick, MD.
H. T. Bausum, S. A. Schaub, K. F. Kenyon, and M. J. Small.
Applied and Environmental Microbiology, Vol 43, No 1, p 28-38, 1982. 2 Fig, 9 Tab, 25 Ref.

Descriptors: *Wastewater irrigation, *Bacteria, *Aerosols, Irrigation, *Land application, Wastewater, Wastewater disposal, Coliforms, Viruses, Coliphage, Public health, Impaired water use.

Land application by spray irrigation has been suggested as an alternative to advance wastewater treatment. However, this procedure entails potential human health hazards due to pathogen-containing aerosols. Data were gathered at a golf course irrigated with secondary domestic wastewater effluent. Bacterial aerosols reached 500 bacteria per cubic meter at 152 meters downwind and 10,500 bacteria per cubic meter at 46 meters. Seeded coliphage f2 averaged 400,000 plaque-forming units per ml in the effluent and were detected 563 meters downwind. Downwind microbial aerosol levels were somewhat enhanced by night time conditions. The median aerodynamic particle size of the microbial aerosols was about 5.0 micrometers. Chlorination reduced wastewater bacterial levels 99.97% and reduced aerosol concentrations to near background levels. Coliphage f2 was reduced only 95.4% in the chlorinated effluent and was readily measured 137 meters downwind. Microbiological source strength and meteorological data were used in conjunction with a dispersion model to generate mathematical predictions of aerosol strength at various sampler locations. The mean calculated survival of aerosolized bacteria in the range 46 to 76 meters downwind was 5.2%, and that of coliphage f2 was 4.3%. (Baker-FRC)

ALFALFA HAY GROWN WITH MUNICIPAL WASTE WATER AND PUMP WATER,
Arizona Agricultural Experiment Station, Tucson.
A. D. Day, R. S. Swingle, T. C. Tucker, and C. B. Cluff.
Journal of Environmental Quality, Vol 11, No 1, p 23-24, 1982. 2 Tab, 11 Ref.

Descriptors: *Wastewater irrigation, *Municipal wastewater, Water reuse, Water conservation, Agriculture, *Alfalfa, Irrigation, Irrigation programs.

The objectives of this research were to compare the quality of a wastewater and pump water mixture with the quality of pump water alone as a source of irrigation water for alfalfa hay production and to compare the yield and quality of alfalfa hay irrigated with a mixture of wastewater and pump water with the yield and quality of alfalfa hay irrigated with pump water alone. The average water penetration into the soil was higher for the wastewater and pump water mixture than for pump water alone. Pump water contained more total soluble salts and nitrate-nitrogen but less total nitrogen and phosphorus than the wastewater and pump water mixture. The general quality of irrigation water was influenced by salt concentrations. High salt concentrations in irrigation water were detrimental to plant growth, as excessive salt levels inhibited germination, limited water uptake and caused specific toxic effects on plants due to ions present in the salts. The wastewater-pump water mixture was a higher quality irrigation source than pump water alone, and was superior for use in growing plants. More phosphorus was deposited on fields irrigated with the wastewater-pump water mixture than was added to fields irrigated with only pump water. This may explain the high levels of extractable phosphorus present in soils irrigated with the wastewater-pump water mixture than were found in soils that received pump water alone. Plants grown with the wastewater-pump water mixture were taller and produced more dry matter in both 1974 and 1975 than did plants irrigated with only pump water. (Baker-FRC)

CASEIN WHEY WASTEWATER EFFECTS ON SOIL PERMEABILITY,

LIBRARY U. OF I., URBANA-CHAMPAIGN

Massey Univ., Palmerston North (New Zealand). Dept. of Soil Science.
K. W. McAuliffe, D. R. Scotter, A. N. Macgregor, and K. D. Earl.
Journal of Environmental Quality, Vol 11, No 1, p 31-34, January-March, 1982. 5 Fig, 1 Tab, 13 Ref.

Descriptors: *Wastewater disposal, *Land disposal, *Wastewater irrigation, Irrigation, *Dairy industry, Irrigation programs, Permeability coefficient, Permeability, Soils, Soil properties, Saturation, Pores.

Experiments are reported to show the changes in soil permeability induced by dairy plant effluent application and to elucidate the mechanisms responsible for the observed changes. Soil cores were collected from a Tokomaru silt loam, a Kopua silt loam and a Manawatu silt loam. A single application of simulated effluent reduced hydraulic conductivity by an average of 46% in the soils. In comparison, cores treated with only water exhibited negligible reduction in hydraulic conductivity. The incorporation of sodium azide (a microbial inhibitor) with the effluent minimized the decline in hydraulic conductivity. Cores that received repetitive effluent applications exhibited an average hydraulic conductivity decline of 99%, whereas cores that received repeated doses of effluent plus inhibitor showed a smaller reduction of 55%. Respirometry studies indicated that the sodium azide did not completely inhibit soil biological activity throughout the entire undisturbed core. It is suggested that the reduction in hydraulic conductivity may reflect a combination of physical and biological processes. Several practical implications were noted. To avoid reduction in saturated hydraulic conductivity an aerobic soil environment should be maintained; thus a land disposal site should never be overloaded so that ponding occurs. An interval between applications is needed to allow hydraulic conductivity recovery. Pore blockage would be lessened, but not eliminated, if suspended solids were removed from the effluent prior to irrigation. (Baker-FRC)

THE OCCURRENCE OF FLOW CHANNELS IN SOILS,
Pennsylvania State Univ., University Park. Inst. for Research on Land and Water Resources.
T. W. Simpson, and R. L. Cunningham.
Journal of Environmental Quality, Vol 11, No 1, p 29-30, January-March, 1982. 1 Fig, 6 Ref.

Descriptors: *Groundwater pollution, *Wastewater irrigation, Channels, Topography, *Water reuse, Saturated flow, Saturation, Water pollution, Soil types, Wastewater disposal.

Investigations were conducted at the Pennsylvania State University Wastewater Irrigation Site which identified soil water flow features described as channels. The site under study has been used as a wastewater disposal area over a 14 year period. Plots received 0, 2.5, or 5 cm of irrigation per week. Some areas only received irrigation water during the growing season. Soil morphology changes were studied and related to changes in time and amounts of wastewater applied. Soil sample cores were also collected from selected horizons of some pits to determine saturated hydraulic conductivity associated with the observed channels. The channels were vertically oriented, variable in size from 50 to 2 cm in diameter, had inverted cone-shaped bodies that had a low bulk density, and were much less firm than the surrounding soil. Many large apparently continuous pores exist in soil material recognized as a channel. Channels usually start in the upper subsoil and extend into lower horizons. Channels range in depth from less than one centimeter to 60 cm. The presence of channels in non-irrigated control areas suggests that their existence may be a natural phenomenon. Channel formation is most likely related to internal erosion of the soil material along structural faces that are coincident with solution channels in the bedrock. Hydraulic conductivity results suggest that the conventional core method may reduce the measured conductivity of the channels. It is evident that the channels are important in water movement at the wastewater irrigation site. If they allow wastewater to leave the biologically active portion of the soil without adequate renovation, groundwater contamination is likely. (Baker-FRC)

DISTRIBUTION OF PHOSPHORUS IN SOILS IRRIGATED WITH MUNICIPAL WASTEWATER EFFLUENT: A 5-YEAR STUDY,
Minnesota Agricultural Experiment Station, St. Paul.
J. J. Latterell, R. H. Dowdy, C. E. Clapp, W. E. Larson, and D. R. Linden.
Journal of Environmental Quality, Vol 11, No 1, p 124-128, January-March, 1982. 1 Fig, 4 Tab, 23 Ref.

Descriptors: *Wastewater irrigation, *Phosphorus, Soil water, Groundwater, Water pollution sources, *Municipal wastewater, Land disposal, Phosphates, Phosphorus removal, *Water reuse.

The objectives of this study were to determine the distribution of various phorphous forms in soil irrigated for 5 years with municipal wastewater and to measure the phorphous-adsorption power of the soil after 5 years of phosphorous loading. The experiment site was adjacent to the Apple Valley, Minnesota wastewater treatment plant, an activated sludge plant with effluent polishing filters. The soil was Waukegan silt loam with a water table at about the 140 to 150 cm depth. Plots receiving comparable quantities of phosphates via wastewater and mineral fertilizer behaved in a similar manner. Plots receiving about two times the above phosphate loading lost some phosphate through leaching to the 60 cm depth. Phosphorus adsorption studies, using the Langmuir equation, showed that the adsorption power of soil in the high rate treatment had been reduced. This was substantiated by the higher phosphorus concentrations noted in soil water at the 60 cm depth in the high treatment areas. (Baker-FRC)

WATER TO THE SOUTH-WESTERN CAPE KEEPING UP WITH THE DEMAND.
Civil Engineering in South Africa, Vol 23, No 11, p 521, November, 1981.

Descriptors: *Water supply development, *Water demand, Water resources development, Water reuse, Rivers, Water desalination, Desalination, *Cape Town, *South Africa.

The demand for water in Cape Town and the South-Western Cape area has forced water planners to consider unconventional water sources, such as recycling or desalination of sea water. The current supply should be adequate until 1988. Only about six conventional sources of water of the South Western Cape remain to be tapped, most of them too small to make a difference. The development of the Cape Flats' groundwater potential is one of the more promising schemes although its potential is limited, with a yield of about 10 million cubic meters per annum. Diverting untapped water out ot the Eerste and Kuils Rivers to supplement the groundwater supply would add about 20 million cubic meters per annum. The Diep River could yield 11 million cubic meters per annum, but the water is brackish and unreliable. Rietvlei, which is fed by the Diep River, could also create an ecological problem if the river were to be dammed. Surplus water in the Berg River could still be tapped, yielding 10 million additional cubic meters per annum. The Lourens River source will yield 10 million cubic meters per annum, but will only be economically viable if done in conjunction with the Ralmiet River Project which would yield 33 million cubic meters per annum. If these sources are tapped and coupled with recycled water usage, the supply could be enlarged to sufficient proportions to meet demand into the end of this century. (Baker-FRC)

IRRIGATION OF CALIFORNIAGRASS WITH DOMESTIC SEWAGE EFFLUENT: WATER AND NITROGEN BUDGETS AND CROP PRODUCTIVITY,
Hawaii Univ., Honolulu. Water Resources Research Center.
L. L. Handley, and P. C. Ekern.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224585, Price codes: A03 in paper copy, A01 in microfiche. Technical Report No 141, December 1981. 29 p, 1 Fig, 8 Tab, 67 Ref, 1 Append. A-075-HI(1), 14-34-0001-9013, -0113.

Descriptors: *Effluent reuse, *Nitrogen cycle, Water budget, Biomass, Pastures, Hawaii, *Impaired water use, *Irrigation practices, *Crop production, Wastewater disposal, *Californiagrass, Nitrogen budget, Tropical grass cultivation, Paragrass, Mililani, Oahu.

Californiagrass (paragrass) irrigated with effluent from secondarily treated domestic sewage showed excellent response as a means for disposal of large amounts of water, effective removal of nitrogen, and high production of excellent fodder. This grass, already well established in Hawaii, is used for pasture and fodder, endures flooding, and because of its allelopathic habit forms dense, easily maintained monostands. The water, nitrogen, and biomass budgets of the grass over a 17-mo period, from April 1979 through August 1980, were measured in eight large percolate-style lysimeters filled with the Lahaina series soil (Tropeptic Haplustox). The experiment was conducted on the grounds of the Mililani Wastewater Treatment Plant in central Oahu, Hawaii. Under irrigation rates which reached as great as 98 mm/day 5 days a week, consumptive use of water by the grass averaged 4 mm/day and was linearly correlated with biomass production. The monthly effluent nitrogen content ranged from 17 to 59 mg/l. With effluent nitrogen application rates which ranged from 475 to 2 600 kg/ha/yr, an average 69% was harvested in the grass, 3% percolated, nearly 28% was denitrofied, while the soi nitrogen status remained unchanged or decreased slightly. Even with the highest effluent irrigation rates, nitrate nitrogen levels in the percolate remained less than the 10 mg/l recommended maximum for potable water. Crop productivity was linear with applied nitrogen. Dry weight averaged 150 tons/ha/yr, with a maximum short-term productivity equivalent to 193 tons/ha/yr. The calculated crude protein content with the highest nitrogen application rates was 13%, while the caloric value was 4 000 kcal/kg, and no nitrate nitrogen levels in the forage exceeded 0.1%.

ABANDONED COAL MINES IN WEST VIRGINIA AS SOURCES OF WATER SUPPLIES,
West Virginia Geological and Economic Survey, Morgantown.
P. Lessing, and W. A. Hobba, Jr.
West Virginia Geological Survey, Circular C-24, 1981. 18 p, 3 Fig, 1 Tab, 1 Append.

Descriptors: *Water supply, *Water use, *Coal mines, Mine drainage, Available water, *Water storage, Precipitation, Infiltration, Selective withdrawal, Wells, Water quality, Water treatment, *West Virginia, Appalachian Plateaus, *Abandoned coal mines.

West Virginia is underlain by numerous beds of coal, many of which have been mined out in places. These underground mines have subsequently been abandoned and are now flooded and/or drain continuously. At present, 72 public water systems supply 8 to 12 million gallons of water per day from abandoned or active mines to 81,600 people and various industrial and commercial establishments. Most of these systems are in southern West Virginia, where the coal contains few sulfur minerals to dissolve and create problems of acid, iron, and sulfate in water. From 5 to 6 inches of precipitation is potentially available annually to seep into underground mine reservoirs. The

amount of water stored in the mine, the rate of infiltration, and the rate of withdrawal determine how much water is available for use. If the water is pumped from a mine by a well, then care must be taken to locate the well in lower parts of the mine, where water tends to accumulate as the water level is lowered by pumping. Some communities using mine water only chlorinate the water, but generally more extensive treatment is required to increase the pH or remove excessive concentrations of hardness, iron, and sulfate. FORAGE PRODUCTION UTILIZING CHEESE PLANT EFFLUENT UNDER HIGH-ALTITUDE CONDITIONS,
Wyoming Univ., Laramie.
M. C. Greene, R. H. Delaney, J. L. Moyer, and J. Borrelli.
Journal of the Water Pollution Control Federation, Vol 52, No 12, p 2855-2864, December, 1980. 4 Fig, 6 Tab, 23 Ref.

Descriptors: *Dairy industry, *Wastewater irrigation, *Nutrients, Effluents, Land application, *Forages, Grasses, Pasture management, Feeds, Irrigation, Nitrogen, Phosphorus, *Impaired water use, Plant growth, Livestock, Water pollution effects, Cold regions, Thayne, Wyoming, Fertilizers.

Effluent from the manufacture of Swiss and mozzarella cheeses was applied to forage plants in laboratory pots and under field conditions. Garrison creeping foxtail, smooth bromegrass, reed canarygrass, tall fescue, meadow bromegrass, alfalfa, and sainfoin were grown in pots under conditions similar to that of the cheese plant irrigation site at Thayne, Wyoming, where there is a 30-day frost free period. No growth inhibitors were present in the cheese plant effluent or a soluttion with the same N, P, and K concentrations (0.1, 0.3, and 61.0 mg per liter, respectively). Highest dry matter production was obtained with a control fertilizer solution with nutrient concentrations suitable for grasses (10.0 mg per liter N, 6.5 mg per liter P, 33.3 mg per liter K, and 45.0 mg per liter S). Most of the grass species watered with effluent contained less protein than the control. Legumes did not show this N deficiency. P content was higher in the effluent-watered plants. Digestibility was not affected by effluent. In general plants grown at 20/10C contained less dry matter, less protein, and less P than plants grown at 23/18C. In the field tests only four of 20 species survived the winter ice pack-- creeping foxtail, reed canarygrass, smooth bromegrass, and western wheatgrass. Creeping foxtail was superior to the others in digestibility and ash content and was well suited to the harsh growing conditions of the irrigation site. Nitrate levels in several species of grass approached levels potentially toxic to cattle, 0.32%. Soil N appeared to become stabilized at the site, but soil P levels increased, especially in the upper soil profile. (Cassar-FRC)

MANAGING SALINITY IN IRRIGATED AGRICULTURE,
Youngstown State Univ., OH. Dept. of Civil Engineering.
I. A. Khan.
Journal of the Irrigation and Drainage Division, Proceedings of the American Society of Civil Engineers, Vol 108, No IR1, p 43-56, March, 1982. 6 Fig, 29 Ref.

Descriptors: *Irrigation efficiency, *Model studies, *Salinity, *Salt balance, Irrigation design, Irrigation practices, Irrigation-return flow, Hydrologic models, Simulation analysis, Optimization, Systems analysis, Groundwater management.

Salt balance is an important factor of any irrigated system. Structural measures to control salt levels in irrigation waters are effective but costly. Excessive accumulation of salts in groundwater and soils is often a problem in irrigated semiarid and subhumid agricultural areas. A non-structural management model is described which may aid in maintaining a permanent irrigated agricultural system at reasonable costs. An optimization model is used to distribute land and water resources, encourage conjunctive use of surface and groundwater, maintain salt movement out of the system, and keep the proper hydrologic balance. Simulation models are employed to assess the impact of agricultural activities on the saturated and unsaturated zones. The whole model operates on the concept that an irrigated system is made up of a number of components, each of which is vital to the smooth operation of the whole system. A simplified version of the model was applied to problems of salinity control in the Pauma, Pala, and Bonsall sub-basins of the San Luis Rey River Basin of Southern California. Model results suggest possible reductions in the normal rate of groundwater depletion by about 80%. (Geiger-FRC)

SEQUENTIAL WATER REUSE EFFECT ON STREAM SALINITY,
Colorado State Univ., Fort Collins. Engineering Research Center.
D. W. Hendricks, C. D. Turner, and D. Klooz.
Water Resources Bulletin, Vol 18, No 2, p 317-324, April, 1982. 6 Fig, 1 Tab, 3 Ref. OWRT A-051-COLO.

Descriptors: *Water reuse, *Salinity, *Irrigation, Water quality, South Platte River, *Colorado, Agriculture, Arid lands, Semiarid lands, Diversion, *Streamflow depletion, Flow regulation, Water storage.

A salinity model based on the water balance principle was developed to estimate the effects of sequential reuse of stream water on residual streamflow and salinity. The salinity increases and streamflow decreases caused by sequential water reuse in arid and semiarid western U.S. areas were shown in an application of the model to the South Platte River Basin, Colorado. The upper limit of total diversions based on minimum streamflow alone was 6,846,900 acre feet per year, which corresponded with an intolerable 5,000 to 10,000 mg per liter dissolved solids. Considering a tolerable salinity of 2600 mg per liter, the upper limit of total diversions was only 5,430,300 acre feet per year. If it was possible to capture an additional 300,00 acre feet per year of excess flow for reuse, 896,100 acre feet more water would be available. (Cassar-FRC)

STRATEGIES FOR REUSE AND CONSERVATION,
Dames and Moore, Houston, TX.
B. P. Popkin.
Water/Engineering and Management, Vol 129, No 3, p 36 40-41, March, 1982. 2 Fig, 2 Tab, 4 Ref.

Descriptors: *Water conservation, *Water reuse, Conservation, Water supply, Nonstructural alternatives, Water demand, Economic aspects, Wastewater renovation, Pricing.

Technological and managerial strategies for municipal water conservation and reuse have been developed. Municipal water conservation and reuse strategies can reduce total and peak water consumptive use and redistribute water use demands. Such strategies can effect water, energy and waste utilities. Water conserving users may find that they incur a net cost burden by conserving and reusing, as service fees increase to offset inflation, expanded services and declining per capita water use. Water management plans and decisions are not based solely on economic analysis, but include many aspects such as multiple objectives, political considerations and historic imperatives. Structural water conservation and reuse strategies are those which consist primarily of the use of hardware and systems. Nonstructural water conservation and reuse strategies are those which consist primarily of software, policies and operations. Examples of devices used in structural water conservation strategies include lawn irrigation timers, swimming pool covers, low-flow shower heads, faucet aerators, toilet and pressure restrictors, and other specialty appliances. Examples of structural water reuse strategies include municipal wastewater and domestic grey-water reuse systems for yard irrigation, municipal wastewater recycling systems for all yard uses, and land application of municipal wastewater for irrigation of recreational facilities. Nonstructural water conservation strategies can incorporate water supply rationing, low minimum water use charges with increasing unit price rates for increasing total water use, seasonal water fees, and high charges and fines for excessive or selected water uses. Numerous economic approaches are useful in any review of water conservation and reuse strategies. (Baker-FRC)

IMPACT OF ENERGY DEVELOPMENT UPON WATER AND SALINITY IN THE UPPER COLORADO RIVER BASIN,
M. Flug, W. R. Walker, and G. V. Skogerboe.
Water Supply and Management, Vol 6, No 1-2, p 199-220, 1982. 8 Fig, 6 Tab, 25 Ref.

Descriptors: *Water resources development, *Mathematical models, *Energy sources, *Salinity, *Colorado River, *Water supply development, *Environmental effects, Water management, Resources management, Model studies, River basins, Policy making, Water policy, Cost analysis, Environmental policy, Available water.

The development and utilization of coal, oil, shale, uranium and energy in the upper Colorado River Basin will create large demands on the available water supply of the region and threaten the quantity and quality of downstream flow. A mathematical model based on a sub-basin analysis of available mineral and water resources was used to simulate the salt and water exchange phase of potential fuel conversion in the river basin. Potential energy developments are examined with respect to the resulting impacts upon both the salinity and quantity of the waters of Colorado River. A multilevel minimum cost of developing predetermined levels of energy output was used to generate model solutions. Results showed that water availability is the most critical factor affecting energy development in the Colorado River. Use of high salinity waters in development policies and interstate water transfers on the Upper Colorado River will allow a net reduction in salinity in waters at Lee Ferry, Arizona, of up to 20 milligrams/liter. use, Consumptive use, Conservation, Water supply, *Municipal water, *Texas High Plains.

Recent studies by the High Plains Study Commission in Texas indicate that a 50% reduction in water use, from 1.38 acre feet per acre to 0.65 acre feet in 2020, would still necessitate a reduction in irrigated acreage in the Texas High Plains, from 6.1 million to 4.9 million acres. A shift to higher value, more water efficient crops would be necessary. In some states where water is abundant, problems occur over ownership of water rights. Facing the problem of interstate transfer of water rights and diminishing groundwater as well as international and interstate compacts affecting the quantity of surface water available from the Rio Grande River, the city of El Paso has attacked the problem of conservation. Homeowners have been encouraged to plant indigenous plants as opposed to high water consuming plants in their yards. Additional measures must be taken in the area of crops and farming to conserve needed water. Consideration is also given to the pricing of water on the basis of how it is used and how much is used. Public opinion must be brought into play to help in cutting down the wasteful application of water. Legal and financial procedures which will allow orderly reordering of water allocations with minimum economic and social penalties are needed. Above all a course of conservation must be taken which avoids consumptive use to the maximum extent and encourages augmentation of existing sources through re-use. (Baker-FRC)

DROUGHT MANAGEMENT: EXPECTING THE UNEXPECTED,
Massachusetts Univ., Amherst. Dept. of Landscape Architecture and Regional Planning.
V. Woo.
Journal of the American Water Works Association, Vol 74, No 3, p 126-131, March, 1982. 2 Fig, 19 Ref.

Descriptors: *Drought, Water management(applied), *Water supply, *Boston, Massachusetts, *San Francisco, California, Planning, Water shortage, Water conservation, Water demand, Water use, Urban areas, Risks.

Implementation of drought management plans in the San Francisco Bay area and in Boston, Massachusetts, produced large and long-lasting reductions in water consumption. In the 1976-77 San Francisco drought, both supply augmentation and demand reduction were used. Water (400,000 acre-feet) was reallocated from southern California to Marin County. The most dramatic reductions in demand occurred in Marin County. At the end of the drought in December 1977 consumers had reduced use there by 60% overall and by 75% among homeowners. Although the commercial and industrial sectors successfully met the requirements of mandatory conservation, they failed to accomplish goals under voluntary programs. A very successful method of promoting conservation was to establish a household water allotment but not dictate the particular use of the ration. As of 1980 water consumption in Marin County was still 22.5% below predought use, and in the East Bay Municipal Utility District, 86-100% of predrought use, without adjusting the figures for an 8.6% increase in connections. These changes in consumption have resulted in the adoption of risk management or incremental planning by some of the California water districts. Boston's 1962-66 drought caused minor economic losses, produced some new installations of long-term benefit, and pointed out idle capacity and inefficiencies. Although demand management appeared to be most suitable for water conservation planning, it was not the city's post-drought response. Instead, physical supply augmentation and incremental adjustments were chosen to supply water for future growth and drought emergencies during the next 10-20 years, considered a transitional period. (Cassar-FRC)

DROUGHT-RELATED WATER CONSERVATION EFFORTS IN MISSOURI,
Tennessee Univ., Knoxville. Dept. of Civil Engineering.
G. D. Reed.
Journal of the American Water Works Association, Vol 74, No 3, p 121-125, March, 1982. 7 Fig, 2 Tab, 13 Ref.

Descriptors: *Water conservation, *Drought, *Water shortage, Water supply, *Missouri, Water consumption, Water demand, Water use, Water management(Applied), Public relations.

During the drought of 1980 water suppliers to Missouri had to implement various water conservation policies with little time for planning. A review of literature on water conservation indicated that voluntary conservation schemes were successful only if accompanied by continous intensive public education and information programs. Pricing schemes, which produced greater use reductions than voluntary schemes, were effective only when the surcharge cost was significant and well-enforced. Answers to a questionnaire to which 31 of 52 Missouri water suppliers responded indicated that 24 suppliers had supply problems and attempted conservation measures. The most common reasons for initating conservation were limitations on treatment and storage facilities (42%) and inadequate raw water (29%). Voluntary conservation was used by 63% and mandatory bans on nonessental uses by 29% of respondents. Most of the failures occured in the voluntary programs. The methods of informing customers of the conservation measures were not as important as the enforcement procedures. None used a water bill surcharge. Seven supliers threatened to disconnect service in case of violation, and none experienced failures in their programs. Eighteen (75%) of suppliers reported successful conservation programs. Most difficulties were experienced by the public water supply districts. The keyto successful conservation programs appeared to be strict enforcement. (Cassar-FRC)

EFFECTS OF POTENTIAL WATER CONSERVATION EFFORTS IN EAST TENNESSEE,
East Tennessee State Univ., Johnson City. Dept. of Environmental Health.
C. S. Bishop, G. T. Broach, W. H. Hester, and V. A. Sikora.
Water Resources Bulletin, Vol 18, No 2, p 189-196, April, 1982. 5 Tab, 15 Ref.

Descriptors: *Water conservation, *Water policy, *Water management, Water use, French-Broad River Basin, Tennessee, Regulations, National Water Policy, Social impact, Economic impact, Institutional constraints, Water supply, Water rates, Wastewater treatment.

The National Water Policy, established during the Carter administration, stressed water conservation on a national scale. The possible positive and negative effects of 10% voluntary reduction and 30% regulated reduction of water usage in the water-rich French-Broad River basin, Tennessee, are described. The two-county basin has abundant rainfall, small-scale agriculture, towns, and industry. With no water conservation in the basin there would probably be no significant environmental, socioeconomic, or institutional changes in the near future. A 10% voluntary reduction would be practical and achievable without producing significant impact on regional economic stability, water rates, or per capita consumption. Possible benefits are improved efficiency and delayed expansion for municipal wastewater treatment plants and improvements in efficiency and life of individual sewage disposal systems. A compulsory 30% water use reduction would be deleterious to social, economic, and political environments. Small marginal industries would close, cutting income of the residents and producing hostility to the plan. Water prices would rise dramatically to compensate for reduced municipal revenues. The local residents are opposed to housing and building codes and other regulations. Before a national conservation policy is implemented further studies must determine regional differences in cultural, social, economic, and institutional factors. (Cassar-FRC)

Descriptors: *Water conservation, *Elasticity of demand, Water use, Water policy, Municipal water, Industrial development, Economic development, Water rates, Domestic water, Arid lands.

The results of this study cast doubt on the widely believed assumption that municipal water supply restrictions and/or conservation policies affect urban growth, at least in western states. A water reduction of 25% would have little effect and would not likely inhibit growth because both household and industrial water demands are quite flexible. Present water use practices are generally wasteful. Water costs in industry are usually a small fraction (on the order of 1%) of total production costs. Neither water quantities nor water prices are likely to deter industries from locating in Western cities. However, cutting water use by 50% or more might discourage persons from moving to Western locations. Hence, there is little reason to oppose moderate water restrictions in fear of inhibiting urban growth or to favor such restrictions in hope of constraining growth. (Cassar-FRC)

INDUSTRY HELPS CONSERVE MUNICIPAL WATER,
Anderson-Nichols and Co., Inc., Providence, RI.
P. R. Levine.
Journal of the American Water Works Association, Vol 74, No 3, p 132-135, March, 1982. 6 Fig.

Descriptors: *Water conservation, *Industrial water, *Water supply, New England, Attleboro, Massachusetts, Fracture permeability, *Groundwater availability, Municipal water, Wells, Groundwater mining, Groundwater sources.

Recent droughts caused the Attleboro, Massachusetts, reservoir to drop far below capacity. An industrial user, which consumed 25% of the city's supply, initiated water conservation measures and searched for alternate supplies. Two measures, employee education and recycling of process and cooling water, reduced use from 2 mgd to 0.85 mgd. No sand or gravel aquifers were found on the site. However, additional groundwater sources were located in fractured regions of bedrock by a new technique, fracture-trace mapping. Aerial photography located these places, which occur throughout New England in lengths of a few hundred feet to several miles. Four wells safely yielded 1 mgd of water if 8 hours rest period was allowed every 4 days. Currently, the manufacturer draws on the municipal water supply only for its potable water needs. Available from the National Technical Information Service, Springfield, VA 22161 as PB82-220658, Price codes: A11 in paper copy, A01 in microfiche. Research Technical Completion Report, May 1981, 238 p, 4 Fig, 64 Tab, 115 Ref. OWRT B-246-IDA(1).

Descriptors: *Drought, *Cropping patterns, *Irrigation practices, Water management, *Crop production, *Idaho, Institutional constraints, Water shortage, Water law, Economic impact.

Survey methods were used in Idaho to document changes in cropping patterns, irrigation systems, and water management strategies caused by the 1977 drought; to document the way management strategies caused by the 1977 drought; to document the way insitutuions such as water delivery organizations and goverment agencies respond to drought; to measure the economic consequences of drought in southern Idaho; to draw implications regarding probable farmer response in future droughts; and to make suggestions for drought management strategies. While some farmers changed crops and varieties or idled land in anticipation of water shortage, the majority proceeded with normal cropping patterns. When water shortage occurred, the result was reduced yield, or in some cases complete loss of the crop. These yield declines and lost crops comprised the largest part of the economic impact of the drought.

LATERAL MOVE IRRIGATION OFFERS ADVANTAGES FOR RECTANGULAR FIELDS.
World Farming, Vol 24, No 1, p 8, 26, 34-35, January/February, 1982.

Descriptors: *Irrigation engineering, *Automation, Linear irrigation, Canals, Farm equipment, Irrigation canals, Mechanical equipment, *Irrigation efficiency, Waker conservation.

The lateral move irrigation system offers many advantages not available in other irrigation systems, especially for large rectangular fields, Uniformity of water distribution increases crop yield by eliminating overwatered and underwatered areas. Fertilizer can be applied through the irrigation system. The linear system irrigates a field twice as fast as surface irrigation and uses 10-60% less water. Heavy, tight soils can be efficiently irrigated by this method bwcause of the low application rates, small droplet size, and low water pressure. The 3 types of linear irrigation systems are based on different types of water pickup. The canal or ditch method, most suitable for level fields, draws water from a canal located at either end or the center of a field. The hose system, useful on sloping fields, uses a high pressure hose, dragged along as the apparatus moves. An underground mainline pipe supplies water through evenly spaced hydrants, to which the system automatically couples and uncouples. Many variations in design are available to suit individual conditions. In addition to the different types of water pickup, there are a variety of nozzles and guidance systems, engines from 45 to 225 horsepower, and pumps from 1600 to 13,300 liters per minute. CUTTING IRRIGATION COSTS,
J. E. Bowen, and B. A. Kratky.
World Farming, Vol 24, No 1, p 14-15, 18-19, 28-29, January/February, 1982. 1 Tab.

Descriptors: *Irrigation efficiency, *Costs, *Pumps, Energy, Surge irrigation, Surface irrigation, Return flow, Water reuse, Maintenance, *Water conservation.

Increasing energy and water costs have forced reevaluation of irrigation practices. Suggestions for saving irrigation costs include: avoid over-irrigation, optimize timing of water application, substitute low-pressure nozzles for high-pressure ones, modify tillage and management practices to reduce runoff, use gravity flow where possible, improve pump efficiency through preventive maintenance, use a return flow system, convert from sprinklers to a surface system, and try the surge flow technique. Windpower can be an alternate energy source for operating hydraulic rams. (Cassar-FRC)

FLEXCROP: A DRYLAND CROPPING SYSTEMS MODEL,
Science and Education Administration, Sidney, MT.
A. D. Halvorson, and P. O. Kresge.
Production Research Report Number 180, April 1982. 49 p, 9 Fig, 10 Tab, 51 Ref, 4 Append.

Descriptors: *Crop production, *Computer models, *Fallowing, *Grain crops, *Soil water, Saline seep, Deep percolation, Soil erosion, *Water use efficiency, Available water, Irrigation practices, *Northern Great Plains.

Wind and water erosion problems along with the development of saline seep areas in the northern Great Plains have made the crop-fallow system of farming undesirable as a farm management practice. Production of small grain or oilseed crops more often than every other year on soils affected by saline seep would reduce the loss of water during fallow by deep percolation, reduce saline seepage, and increase water-use efficiency. A flexible cropping system should consider the amount of plant-available soil water at seeding time; estimated average growing season precipitation; and grower management factors. Summer fallowing should be done only when water is so deficient that the probability of producing a profitable crop is low. A dryland cropping system computer model, 'FLEXCROP', was developed to help farm managers evaluate the effects of their crop and soil management decisions on potential crop yield and to help them decide whether to recrop or summer fallow a given field. Winter wheat, spring wheat, barley, oats, and safflower are the crops covered in the current model. (Moore-SRC)

Descriptors: *Peanuts, *Irrigation practices, *Crop yield, *Evapotranspiration potential, *Growth stages, Irrigation, Plant growth, Irrigation efficiency, Irrigation effects, Irrigation operation, Water requirements, Evapotranspiration, Irrigation requirements, Agricultural hydrology, Assessments, Irrigation water, Transpiration.

A study was conducted to determine the optimum irrigation schedule for peanuts at different crop growth stages, using two peanut varieties (Spanish and Florunner) evaluated under seven different irrigation treatments. The treatments included a no-stress check treatment and a dryland treatment. Each treatment had a different schedule of either irrigating or stressing the peanut plant during one or more of three crop growth stages. For the Spanish variety: providing irrigation only during the pegging stage produced 394 kg/ha higher yield than irrigating during the early maturation stage; pegging stage irrigation treatments had an evapotranspiration amount at least 25 mm greater than treatments with no irrigation at this stage. For the Florunner variety: treatments which had an irrigation during the late maturation stage produced near maximum yield even though some treatments had a drought period; treatments having an irrigation during this stage had a steady evapotranspiration rate. The effects of other treatment schedules at other growth stages are also discussed. Recommendations for futher studies are provided. (Zielinski-MAXIMA)

A REPORT ON: RESEARCH NEEDS....WATER CONSERVATION IN AGRICULTURE,
E. A. Hiler.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224833, Price codes: A03 in paper copy, A01 in microfiche. Report, July 1978. 29 p, 10 Ref. (No 8542)(1).

Descriptors: *Water conservation, *Water supply development, *Irrigation efficiency, *Research priorities, *Systems analysis, Assessments, *Agriculture, Water requirements, Irrigation requirements, Water storage, Water conveyance, Water management, Irrigation programs, Irrigation practices, Water control, Farms, Groundwater recharge, Optimization.

Current situations in various areas of two major categories related to water conservation in agricultural operations are assessed, with generally 3-6 critical themes identified in each area where research is most needed. The first major category (water source augmentations and improvements in off-farm delivery systems) addresses six water conservation areas (storage and conveyance; groundwater replenishment; improved water control and measurement structures; soil water; increasing and

LIBRARY U. OF I., URBANA-CHAMPAIGN

regulating streamflow; sediment reduction; improving economic and institutional arrangements). The second major category (improved on-farm water management related to irrigation scheduling and efficient systems) addresses three water conservation areas (irrigation water use efficiency; salinity control/management efficiency; optimizing crop water use). It is pointed out that isolated problem-solving can effect a slight change that may cause undue stress elsewhere in the entire system. Systems analysis is proposed as a means for viewing the entire water management problem. Specific research needs in systems analysis and a generalized approach for its use are also included. (Zielinski-MAXIMA)

IMPROVED WATER AND NUTRIENT MANAGEMENT THROUGH HIGH-FREQUENCY IRRIGATION, VOL. 3: DETERMINING THE TRANSPIRATION RATE OF PEACH TREES UNDER TWO TRICKLE IRRIGATION REGIMES,
Texas A and M Univ., College Station.
T. A. Howell, M. J. McFarland, D. L. Reddell, K. W. Brown, and R. J. Newton.
Available from the National Technical Information Service, Springfield, VA 22161 as Price codes: A04 in paper copy, A01 in microfiche. Technical Report No 113, Vol 3, December, 1980. 56 p, 8 Fig, 7 Tab, 19 Ref, 1 Append. OWRT B-219-TEX, 14-34-001-8121.

Descriptors: *Transpiration, *Evapotranspiration potential, *Trickle irrigation, *Peaches, *Irrigation efficiency, Evapotranspiration, Soil moisture retention, Rainfall rate, Irrigation effects, Irrigation operation, Irrigation practices, Irrigation requirements, Nutrient requirements, Water requirements, Crop yield, Plant growth, Trees, Water conveyance, Agricultural hydrology, Hydrologic aspects, *Texas.

Research was carried out to quantitatively determine the transpiration rate of two trickle irrigation treatments in a northcentral Texas peach orchard. A soil water balance method was used to determine evapotranspiration (ET). One treatment (II) irrigated at a calculated rate (the measured pan evaporation, times the surface area inside the tree drip line, multiplied by a replenishment factor of 0.6) through two emitters; the other treatment (I) received half the calculated rate, distributed through one emitter. Treatment II may have had a more extensive root distribution than I, as indicated by observed moisture extraction patterns. The tree in each treatment could obtain moisture stored in the root zone. Both treatments had an ET rate considerably greater than their irrigation rates. However, the ET rates of both treatments were below the potential ET. Estimates of the transpiration rates of treatments I and II were 1.6 and 3.5 mm/day, respectively. Determinations of ET were based upon determinations of the change in soil moisture, and the levels of rainfall and irrigation. Recommendations of future research and design criteria areas based on the results of these studies are delineated. (Zielinski-MAXIMA)

IMPROVED WATER AND NUTRIENT MANAGEMENT THROUGH HIGH FREQUENCY IRRIGATION,
Texas A and M Univ., College Station.
T. A. Howell, K. W. Brown, R. J. Newton, D. L. Reddell, and M. J. McFarland.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224866, Price codes: A02 in paper copy, A01 in microfiche. Summary Report for Technical Report No 113, March 1981. 12 p, 1 Fig, 3 Tab, 2 Ref. OWRT B-219-TEX, 14-34-0001-8121.

Descriptors: *Irrigation efficiency, *Irrigation practices, *Nutrient requirements, *Crop yield, *Plant growth, Irrigation effects, Irrigation operation, Irrigation requirements, Sprinkler irrigation, Trickle irrigation, Peanuts, Peaches, Trees, Water requirements, Water conveyance, Water supply, Soil moisture retention, Agricultural hydrology, Hydrologic aspects, Nitrates, Water allocation, Water conservation, Sorghum, *Texas.

Research was directed toward defing the best management practices for irrigation timing and fertilizer applications under high frequency irrigation. Following a comparison of methods for determining soil hydraulic properties (Vol. I), research was conducted on a comparison of peanut water use efficiencies under differing sprinkler irrigation regimes (Vol. II), on an evaluation of water requirements by peach trees under trickle irrigation (Vol. III), and on a determination of nutrient and water requirements relative to grain sorghum response (Vol. IV). Irrigation water was pumped from the Brazos River into a lined pond, filtered, and pumped by turbines for the trickle system and for sprinkler, micro-basin, and furrow plots. An automatic weather station monitored climatic conditions, and soil samples were routinely analyzed for nitrogen content. The research results demonstrated high frequency irrigation to be a proven management system with several advantages. It has the potential for significantly increasing crop yield by application of a relatively small percentage of the total water requirement. The rainfall regime must, however, be favorable for the value of high frequency irrigation studies to be quantifiable. (Zielinski-MAXIMA)
W82-05313

SOIL WATER INTAKE RATES AND SURFACE IRRIGATION SYSTEM CHARACTERISTICS BY SOIL SERIES IN SOUTHEASTERN IDAHO,
Idaho Univ., Moscow. Coll. of Engineering.
K. H. Yoo, and J. R. Busch.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-236548, Price codes: A05 in paper copy, A01 in microfiche. Report, March, 1981. 84 p, 4 Fig, 7 Tab, 12 Ref, 4 Append. OWRT B-041-IDA(3).

Descriptors: *Soil water, *Soil types, *Intakes, *Surface irrigation, *Irrigation practices soil water potential, Loam, Soil texture, Hygroscopic water, Agricultural runoff, Experimental design, Agricultural hydrology, Soil conservation, Crop yield, Field capacity, Testing procedures, Field tests.

Seven major soil series of irrigated agricultural land in southeastern Idaho, ranging from silt loam to gravelly loam in texture, were evaluated to obtain soil water intake rates. Three crops (hay, grain, and poatoes) were selected for the study, and soil survey maps from the local Soil Conservation Service were used to locate each area soil series. Since it was difficult to select representative sampling sites in a given field, it was necessary to test several different sites to obtain average results. Irrigation practices evaluated on two furrow fields from data obtained in the study revealed that improved water management practices are needed on both fields to obtain higher application efficiencies. One field had excess irrigation with high runoff loss; the other had a lack of irrigation with high runoff loss. Application efficiency could be increased by using a cut-back stream and/or a return flow recovery system. To assess border irrigated fields the infiltrometer ring test (RT) was used; for furrow fields, the inflow-outflow (IO) method was used. Potato fields generally had lower intake rates than other crops by the RT method. Intake rates for furrow-irrigated potato fields differed between those obtained by the RT and those obtained by the IO method. While the IO method has been known as the most dependable for obtaining intake rates, under some conditions the RT is a simpler and easier method. (Zielinski-MAXIMA)

OPTIMIZING THE USE OF WATER AND NITROGEN THROUGH BREEDING OF CROPS,
Commonwealth Scientific and Industrial Research Organization, Canberra (Australia). Div. of Plant Industry.
R. A. Fischer.
Plant and Soil, Vol 58, No 1-3, p 249-278, 1981. 9 Fig, 3 Tab, 55 Ref.

Descriptors: *Crop production, *Water use efficiency, *Crop yield, *Water stress, *Nitrogen, Transpiration, Wheat, Barley, Arid zones, Soil-water-plant relationships, Water uptake, Plant growth, Drought resistance.

Breeding of special wheat and barley cultivars has increased crop yield in certain Mediterranean type environments over the past 20 years. The black box approach to drought resistance examines the yield differences of crops in terms of underlying process differences. Dwarfing of wheats has significantly increased their yield in arid regions. The ideotype approach to drought resistance and trait formulation, based on field measurements, is described. Encompassed in this approach are the effects of water limitation, crop transpiration, and the maximization of the harvest index. Optimal flowering date strategies, preanthesis water stress, and hot spell damage are also discussed. Ideotype testing is often limited by lack of rapid screening methods. The impoved nitrogen utilization efficiency of higher yielding cultivars is related to more grain per unit of nitrogen taken up by the crop rather than to more nitrogen uptake. Genotype selection may help overcome water stress injury due to high plant nitrogen content. (Geiger-FRC)
W82-05608

OPTIMIZING THE USE OF WATER AND NITROGEN THROUGH SOIL AND CROP MANAGEMENT,
Oregon State Univ., Corvallis. Dept. of Crop Science.
F. E. Bolton.
Plant and Soil, Vol 58, No 1-3, p 231-247, 1981. 4 Fig, 3 Tab, 34 Ref.

Descriptors: *Crop production, *Water use efficiency, *Soil management, *Nitrogen, Soil water, Arid zones, Fertilizers, Water use, Weed control, Water storage, Transpiration, Soil-water-plant relationships, Planting management.

Under rainfed production of crops, water must be used efficiently to optimize water and nitrogen supplies. To accomplish this, maximum amounts of water can be stored in the soil profile by improved tillage and moisture conservation practices while maximum use is made of stored water through improved crop management practices. In semi-arid, rainfed regions, fertilizer applications should be based on current moisture supplies rather than long-term averages. The 'package of practices' approach involves utilizing the best combinations of tillage, selection of adapted varieties and optimum planting and fertilizer application times, and weed control and harvesting techniques. The proper package of practices must be determined in extensive field studies conducted over a long period of time. Each element in the production package must be performed in the proper sequence or to the advantage of the other elements. Since many resources such as fertilizers and herbicides are not presently available in the developing countries, implementation of the complete production package in these nations is not yet feasible. Use of some elements of the production package which fit into the traditional system may offer substantial increases in yield until other elements of the production package are applied at a later date. (Geiger-FRC)

PLANT IMPROVEMENT FOR SEMI-ARID RANGELANDS: POSSIBILITIES FOR DROUGHT RESISTANCE AND NITROGEN FIXATION,
Utah State Univ., Logan. Crops Research Lab.
D. A. Johnson, M. D. Rumbaugh, and K. H. Asay.
Plant and Soil, Vol 58, No 1-3, p 279-303, 1981. 3 Fig, 98 Ref.

Descriptors: *Range management, *Semiarid lands, *Grazing, *Drought resistance, *Vegetation regrowth, Range grasses, Water stress, Water deficit, Drought, Nitrogen, Legumes.

As world population increases, so should the importance of semi-arid rangeland for off-season livestock grazing in rotation with croplands. Improved plant materials and better grazing management practices are needed to rectify problems caused by underproduction due to overgrazing. The development of drought-resistant range plants is being studied through drought characterization, defini-

tion of selection criteria, assemblage of a broad genetic base, and the development and application of screening methods. Since plant productivity on many arid rangelands is limited by nitrogen, legumes should be evaluated to assess their potential for contributing nitrogen to the rangeland environment. Interdisciplinary programs should be tested to bring about plant improvement under drought stress to develop cultivars suitable for the re-vegetation of semi-arid rangelands. (Geiger-FRC)

ADVANCE AND RUNOFF-SURGE FLOW FURROW IRRIGATION,
Utah State Univ., Logan. Dept. of Agricultural and Irrigation Engineering.
P. S. Coolidge, W. R. Walker, and A. A. Bishop.
Journal of the Irrigation and Drainage Division, Proceedings of the American Society of Civil Engineers, Vol 108, No IR1, p 35-42, March, 1982. 2 Fig, 2 Tab, 7 Ref.

Descriptors: *Furrow drainage, *Irrigation efficiency, *Irrigation design, *Irrigation requirements, Furrow irrigation, Furrows, Surges, Irrigation ditches, Irrigation return flow, Irrigation practices, Irrigation engineering, Irrigation water, Water conservation.

Furrow advance and runoff studies were conducted on a field of silt loam soil using pulsed water applications. The surge flow irrigation method, defined as the intermittent application of water to furrows or borders creating a series of on and off modes of constant or variable time spans, was applied in two experiments each covering 100 m furrow sections. The first experiment tested 13 combinations of on-and off-times, each replicated 5 times. The second investigation consisted of 10 combinations of cycle period and cycle ratio with two replications. Results showed that the application of surge flow irrigation significantly accelerated furrow advance per unit of water used while reducing the temporal and spatial variability among furrows in the field. It was suggested that furrow drainage between surges accelerated the formation of thin surface seals, thereby reducing intake rates. (Geiger-FRC)

Journal of the Irrigation and Drainage Division, Proceedings of the American Society of Civil Engineers, Vol 108, No IR1, p 57-74, March, 1982. 4 Fig, 3 Tab, 25 Ref.

Descriptors: *Mathematical studies, *Evapotranspiration, *Irrigation requirements, *Irrigation efficiency, *Model studies, Evaporation, Evapotranspiration potential, Irrigation programs, Irrigation water, Mathematical models, Crop production, Transpiration.

New crop coefficients for the Pacific Northwest irrigated crops of alfalfa, potatoes, snap beans, sugar beets, sweet and field corn, garden peas, winter and spring wheat, and spring barley were developed for use in the relationship describing evapotranspiration (ET). Reference ET was based on the ET rate for well watered, actively growing alfalfa in arid, irrigated regions. The improved ET coefficients represent basal or minimal coefficients reflecting conditions of minimal soil evaporation, but adequate root zone moisture. They can be used with the United Stated Department of Agriculture Computerized Irrigation Scheduling Program for estimating daily crop ET. When combined with improved estimates of evaporation from wet soils, the new coefficients should permit more accurate estimates of daily crop ET, and irrigation water requirements and thus more accurate irrigation scheduling. New crop models are needed to permit partitioning soil evaporation and plant transpiration, and to provide a basis for directly relating the crop coefficient to crop development. (Geiger-FRC)

IRRIGATION EFFICIENCY IN ORCHARDS,
Department of Agriculture, Summerland (British Columbia). Research Station.
D. S. Stevenson.
Canadian Water Resources Journal, Vol 5, No 3, p 102-110, 1980. 4 Tab, 1 Ref.

Descriptors: *Irrigation efficiency, *Orchards, *Fertilizers, Apples, Water use, Summerland, *British Columbia, Fruit crops, Water conservation, Irrigation techniques, Lysimeters, *Canada.

The term irrigation efficiency encompasses four interrelated factors: efficiency of water use, efficiency of labor, efficiency of dollars, and efficiency of land. Orchardists in British Columbia's arid Okanagan Valley traditionally overirrigate, wasting 50% of the water applied, losing fertilizer, and changing soil chemistry. Possible solutions to this are increased capacity of the irrigation system so that irrigation can be done quickly and less frequently and conversion from sprinklers to trickle irrigation. In the Summerland District 12 lysimeters planted with McIntosh apple trees were used to study irrigation efficiency and fertilizer application. Application rates were equivalent to 3.6 mm per day (37% of usual irrigation allotment) in 1974-77; 4.6 mm per day in 1978-79. In these 6 years very little drainage was obtained from silt soils. Drainage from sandy loam soils was 13-38% of total applied water on bare ground and 1-31% of total applied water on grass covered lysimeters. Amounts of nitrogen fertilizer reaching the groundwater were about 50% for cultivated soil and 5-15% for grass covered soil. (Cassar-FRC)

THE WELLTON-MOHWAK DILEMMA,
Science and Education Administration, Riverside, CA. Salinity Lab.
J. Van Schilfgaarde.
Water Supply and Management, Vol 6, No 1-2, p 115-127, 1982.. 2 Fig, 5 Tab, 9 Ref.

Descriptors: *Irrigation effects, *Salinity, *Irrigation efficiency, *Desalination plants, *Economic aspect, *Colorado River, Desalination, Water management, Irrigation programs, Irrigation practices, Irrigation water, Irrigation-return flows, Rate of return, Water pollution sources.

The Wellton-Mohawk irrigation project near Yuma, Arizona involves the conveyance of Colorado River waters to lands in and above the Gila River Valley. To alleviate waterlogging and salinity problems caused by the project, numerous pump drains were installed, which resulted in significant increases in the salinity levels of downstream waters in the Mexicale Valley. The United States has planned an expensive desalting plant to upgrade water salinity levels to be in accordance with the 1973 Water Treaty with Mexico. Improving irrigation management practices in the area of the Wellton-Mohawk project was considered a more cost-effective approach, but one that was difficult to implement based on economic return. If irrigation efficiency is increased and return flows decreased, the size of the proposed desalting plant may be reduced. (Geiger-FRC)

SALINITY CONTROL MEASURES FOR GRAND VALLEY,
Colorado State Univ., Fort Collins. Dept. of Agricultural and Chemical Engineering.
G. V. Skogerboe, W. R. Walker, and R. G. Evans.
Water Supply and Management, Vol 6, No 1-2, p 129-167, 1982. 14 Fig, 7 Tab, 28 Ref.

Descriptors: *Desalination, *Irrigation effects, *Colorado river, *Salinity, *Irrigation efficiency, *Irrigation-returnflow, *Canal linings, Water quality control, Groundwater management, Irrigation engineering, Irigation canals, Irrigation practices, Saline water, Irrigation water, River basins, River basin development.

Irrigation return flows which contact the marine deposited Mancos shale enter aquifers of the Grand Valley in west central Colorado and cause excessively saline waters to reach the Upper Colorado River Basin. Various measures are studied for reducing the salt load from this area. On-farm improvements to reduce irrigation return flows include irrigation scheduling, head ditch linings, and sprinkler and trickle irrigation. Other approaches are conveyance channel linings, field relief drainage, taxation and land retirement, modified legal constraints, and collection and desalting of return flows. A restructuring of the local irrigation system lying below the turnouts from the major canal systems would be the best procedure for salinity control in the waters of the Grand Valley. At higher levels of valley-wide salinity control, emphasis should be placed on canal linings for other irrigation canals in addition to the Government Highline Canal. Only after major irrigation system improvements are implemented would desalination become a cost-effective means of salinity control. (Geiger-FRC)

4. WATER QUANTITY MANAGEMENT AND CONTROL

4A. Control Of Water On The Surface

ON-SITE STORMWATER DETENTION: AN OVERVIEW,
Texas A and M Univ., College Station. Dept. of Civil Engineering.
J. M. Mason, Jr.
Public Works, Vol 113, No 2, p 62-64, February, 1982. 2 Fig, 3 Ref.

Descriptors: *Storm water, *Runoff, Flood control, Storm runoff, Detention reservoirs, *Urban runoff, Surface runoff, Dry wells, Trenches, Ditches, Economic aspects, Ponds, Cisterns, *Sewer systems, *Water pollution control.

Street runoff is composed of many pollutants also found in sanitary sewage, along with considerable amounts of metals. Various measures may be taken to collect contaminants before they enter the sewer system. The objective of detention facilities in general is simply to regulate the runoff from a storm by distributing it over a longer time period. Methods include surface storage using dry ponds, wet ponds, parking lots, shallow surface catchments, and subsidiary fill impoundments; rooftop storage; underground storage with trench, pipe and cistern storage and tunnel-reservoir systems; and infiltration storage such as dry wells and infiltration trenches. To control the discharge from small on-site detention basins, a number of outlet structures are needed: pipe/culvent, perforated riser pipe, weir, or a special outlet control box. An emergency spillway must be provided in the event of a critical storm that exceeds the basins's design frequency. The preferred location of an emergency spillway is on undisturbed ground rather than over a prepared embankment. The emergency spillway must be sufficiently protected to eliminate any potential erosion. Efforts should be made to direct the spillway away from high value property and toward the natural drainage pattern. Economic justification for constructing the facilities for control of stormwater runoff has been that they enhanced the value of the areas affected. Other benefits would be the creation of recreation areas and the replenishment of the ground water supply. Identifying the beneficiaries of flood and pollution control projects is an important consideration in allocating the costs of such improvements. (Baker-FRC)

PREDICTION OF WATER LEVEL IN TIDAL INLET,
Kanazawa Inst. of Technology (Japan). Dept. of Civil Engineering.
K. Mizumura.
Journal of the Waterway Port Coastal and Ocean Division, Proceedings of the American Society of Civil Engineers, Vol 108, No WW1, p97-106, February, 1982. 13 Fig, 10 Ref.

Descriptors: *Model studies, *Intake gates, *Water level fluctuations, *Tides, *Lakes, *Regression analysis, Mathematical models, Hydraulic models, Irrigation water, Filtration, Mathematical studies, Inlets, Theoretical analysis, Markov process, Prediction, Tidal lakes, Lake Kahokugata, *Japan.

In order to control the water quality and quantity of tidal lakes, the operation of gates at the inlets must be undertaken with extreme care. Water flow through the inlet must be sufficient for crop irrigation without being high enough to cause flooding. In order to optimize gate control, water levels downstream are predicted by a combined model which uses regression theory and control theory. In the first part of this two part model, a regression equation is used along with sea levels to predict the water levels downstream of the gate. In the second part, a Kalman filtering algorithm is utilized to identify parameters used in constructing the state equation . The model was applied to problems of estimating water levels on the downstream side of the gate at the Lake Kahokugata inlet in Ishikawa, Japan. It was possible to determine changes in water levels under the arbitrary gate operations one or two hours before the actual water fluctuation events. Use of Kalman filtering made possible the realtime prediction of water levels when the second order Markov model was employed. (Geiger-FRC)

MAN-MADE STORAGE OF WATER RESOURCES--A LIABILITY TO THE OCEAN ENVIRONMENT. PART II,
Bedford Inst. of Oceanography, Dartmouth (Nova Scotia).
H. J. A. Neu.
Marine Pollution Bulletin, Vol 13, No 2, p 44-47, February, 1982. 2 Fig, 6 Ref.

Descriptors: *Water storage, *Environmental effects, *Seasonal variation, Balance of nature, Hydroelectric power, Salinity, Canada, Reservoirs, Water resources development, Estuaries, Fisheries, Marine fisheries, Runoff, Marine biology, Powerplants, *Regulated flow, *Ecological effects, Ocean circulation.

Regulating natural seasonal runoff for power production may product serious damage to marine life. Biological activities in large ocean currents such as the Gulf Stream depend on a seasonal nutrient supply, which in turn is regulated by the seasonal fresh water runoff. Modifications of these patterns, which have evolved over thousands of years, may be responsible for declines in fish catches, as seen in the late sixties and early seventies off the North Atlantic Coast. Other areas where marine life has been disturbed by water resources development are the Nile Delta, the Black and Azov Seas, and the Grand Banks of Newfoundland. Over 300 water storage projects have been built in Canada during the last 25 years. This has changed the balance of water storage in this region from the natural ratio of 4:1 (summer:winter) to 3:2. Possibilities for achieving more natural seasonal flows are power production without storage (run of the river stations), closed-circuit twin lake systems in which water is pumped into the upper lake during periods of low power demand and excess available energy, and determining the minimum spring flow necessary to maintain primary production in estuaries. DEVELOPMENT OF NATURAL SUBIRRIGATION OF LANDS AND ITS PREDICTION NEAR LARGE RESERVOIRS,
Northern Scientific Research Inst. of Hydraulic Engineering and Reclamation, Kazan (USSR).
G. N. Petrov.
Water Resources, Vol 8, No 2, p 155-164, March-April, 1981. 4 Tab, 9 Ref. Translated from Vodnye Resursy, No 2, p 98-108, March-April, 1981.

Descriptors: *Waterlogging, *Reservoirs, *Subirrigation, Soil water, Environmental effects, *Dam effects, Drainage, Hydrophytes, Swamps, Wetlands, Water level fluctuations, Capillary water, Saline soils, Demineralization, Vegetation, Soil saturation, *USSR.

Natural subirrigation, an adverse result of building reservoirs on flatland rivers, may affect areas of 0.5 to 3000 ha, according to investigations of several large reservoirs in Russia. A consequence of subirrigation is waterlogging of the soil, leading to the development of swamps, increase of soil acidity, salinity, gleization, and transformation into meadows. A succession of vegetation from mesophilic to hydrophilic occurs over a number of years. Several conditions which promote the development of subirrigation are: increase in humidity on the low windward shores, wind-induced denivellation phenomena accompanied by tilting of the water surface and flooding, raising the reservoir level above normal, daily and weekly variations up to 1 m of the water level, closed small depressions, rapid spread and slow decomposition of hygrophytes with tubers and rhizomes, disturbance of soil by grazing cattle, enclosing subirrigated lands (which encourages deposition of debris), existence of low spots many km from the reservoir, and fine-textured soil. Studies on prediction of subirrigation are described. (Cassar-FRC)

THE UTILIZATION OF GRASS CARP, CTENOPHARYNGODON IDELLA VAL., FOR HYDRILLA CONTROL IN LAKE BALDWIN, FLORIDA,
Florida Univ., Gainesville. School of Forest Resources and Conservation.
J. V. Shireman, and M. J. Maceina.
Journal of Fish Biology, Vol 19, No 6, p 629-636, December, 1981. 3 Fig, 3 Tab, 15 Ref.

Descriptors: *Vegetation, *Fish, *Aquatic weed control, Aquatic plants, *Water pollution control, Eutrophication, *Florida, Lakes, Lake Baldwin, Carp, Hydrilla, Plant growth.

The effectiveness of grass carp in control of hydrilla was investigated by stocking Lake Baldwin, Florida with this control agent during 1978 at a rate of 24 fish per ha. At two years after stocking, hydrilla was nearly eradicated from the lake. Control was effective with 130 kg grass carp/ha of hydrilla, and control was definite when biomass exceeded 185 kg/ha of hydrilla. During the first two years the growth of grass carp was rapid,as the fish reached 9.17 kg by June of 1980. Grass carp greater than 6 kg in weight consumed 25-28% of their body weight of hydrilla per day. The use of grass carp for vegetation management is discussed. It is proposed that three methods can be used to manage vegetation with grass carp; method selection depends on the management goal. First, stock sufficient grass carp to completely remove vegetation. Second, stock grass carp in low numbers to remove vegetation at a slow rate which achieves desired vegetation levels after three to four years and adjust grass carp numbers as needed. Or, third, use chemical or mechanical methods to achieve control within the first year and stock only enough grass carp to maintain this level. The third option appears to offer the best possibilities. Grass carp should be stocked (0.5 kg) during the first winter at 5-6 fish/ha of hydrilla. This should be sufficient to consume regrowth. (Baker-FRC)

SEASONAL RISK-BASED RESERVOIR OPERATING RULES,
Colorado State Univ., Fort Collins. Dept. of Civil Engineering.
T. P. Ballestero.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224742, Price codes: A10 in paper copy, A01 in microfiche. PhD. Thesis, Spring 1981. 189 p, 108 Fig, 9 Tab, 61 Ref, 4 Append. OWRT B-195-COLO(4).

Descriptors: *Reservoir operation, *Operating policies, *Probabilistic process, *Risks, *Seasonal variation, Economic aspects, Reservoir storage, Water storage, Reservoirs, Management planning,

Planning, Estimating, Priorities, Prediction, Forecasting, Projections, Policy making, Water supply systems, Water supply, Water scarcity, Water loss, Water management, *Hazardous materials, Spills.

Research was carried out to develop a capability to predict short-term (seasonal) effects of various reservoir operation policy on future failure (spill or deficit) probabilities, based on application of the concept of the Anticipated Decision Influence Period (ADIP). The ADIP is defined as the time from the present to the end of the current failure (spill or deficit) period. Three methods of identifying the ADIP and two types of risk-based rule schedules were tested. Two reservoirs were analyzed: one with almost insignificant overyear storage; one with considerable overyear storage. It was concluded that the risk-based rules yield improvement over standard normal conditions for the small reservoir, with improvements being magnified for the large reservoir. Three steps were used to formulate reservoir policy based on the future failure volume distribution and implementation of the policy if future failure probability criteria were violated. This was followed by the mapping out of the results of various levels of action to decrease future failure risk. Thus, future failure risk may be decreased and the magnitude of the decrease may be controlled. (Zielinski-MAXIMA)

INTEGRATED MANAGEMENT OF WATER DEFICITS AND FLOODS IN A RESERVOIR SYSTEM,
Centro Teoria dei Sistemi, Milan (Italy). Ist. di Elettrotecnica ed Elettronica.
P. Bolzern, G. Fronza, F. Garofalo, and G. Ambrosino.
Journal of Environmental Management, Vol 13, No 1, 1981. p 1-12. 3 Fig, 1 Tab, 16 Ref.

Descriptors: *Reservoirs, *Flood control, Mathematical studies, *Statistical methods, Stochastic processes, Management planning, Multipurpose reservoirs, Reservoir storage, Reservoir yield, Simulation analysis, *Optimization, Systems analysis, Flood data, *Reservoir operation.

A reservoir management approach is described. The approach assumes that inflow forecast is one of the driving variables of reservoir operation and avoids fixing a minimum advisable freeboard. The design also takes into account both short- and long-term objectives, specifically, mitigation of downstream water deficiencies and mitigation of flooding adjacent to the reservoir. The first goal is addressed in an optimization model which prescribes a schedule of releases on the basis of current storage and forecast inflows. The second goal is addressed in daily yield decisions based on flood control requirements. (Titus-FRC)

FLOOD CONTROL AND FLOW REGULATION PROBLEMS ON THE ASSINIBOINE RIVER,
Manitoba Dept. of Natural Resources, Winnipeg.
N. Mudry, G. H. MacKay, and V. M. Austford.
Canadian Water Resources Journal, Vol 6, No 4, p 157-173, 1981. 1 Fig, 4 Ref.

Descriptors: *Flood control, *Water management, *Enviromental effects, Diversion structures, Flood protection, Flow regulation, *Assiniboine River, *Manitoba, Floodways, Flood channels, Reservoirs, Sheelmouth Dam, Brandon, Winnipeg, Portage-la-Prairie, Land acquisition, Water conveyance, Water quality, Drainage, Water supply, Intakes, Flood plains, River basins, Water resources development, Canada.

Several unanticipated problems have resulted from the flood control and flow regulation projects on the Assiniboine River in the Winnipeg, Manitoba, region. The control structures include a floodway to divert Red River water around Winnipeg, a diversion channel to convey floodwaters from the Assiniboine River to Lake Manitoba, the 35-mile long Shellmouth Reservoir on the upper reaches of the river, and a dike system within Winnipeg and in agricultural regions between Portage-la-Prairie and Winnipeg. Criteria for land acquisition at the head of the reservoir were relaxed to allow private ownership of 160-200 ha of 607 ha of marginally affected land below the 431.3 m level. This was a mistake, because the drainage time on this land was substantially increased after reservoir construction. Flooding and impeded drainage have also increased in cultivated land directly downstream from the dam. Adjustment of flow rates to solve this problem would greatly increase flooding further downstream. The major algae blooms on the reservoir have affected municipal water supplies as far downstream as Brandon, especially at flows of 8.5 cu m per sec or less. A winter water supply intake for the Portage-la-Prairie municipal supply does not perform as designed because flow fluctuations and high silt levels cause damage and operational problems in the pumping system. In addition, heating of equipment and a larger staff are necessary. There is also a danger of ice damage to the conduit gate. The diversion channel to Lake Manitoba has caused silt damage and poor drainage in adjacent farmlands. Since the government did not buy all the land for the Assiniboine River dike system prior to construction, there have been problems with farmers removing dikes, with dike maintenance, and with subsequent land acquistion. CALIFORNIA'S PERIPHERAL CANAL: SKIRTING THE DELTA - AND THE ISSUES,
T. Pfaff.
Environment, Vol 24, No 3, p 25-35, April, 1982. 6 Fig, 22 Ref.

Descriptors: *Water resources development, *Canals, *California, Peripheral canal, *Sacramento River, Construction, Financial aspects, Public opinion, Ecological effects, Planning, Diversion structures.

The proposed peripheral canal to be built in California is described. The canal would be the largest public works project in world history. The issue is complex and needs to be viewed from many perspectives. An overview of the state's geography and hydrology is an important factor. At its proposed size the canal would have an annual capacity of 16.3 MAF of water. At peak operating levels it could divert as much as 70% of the Sacramento River's average flow. From the start environmentalists have expressed concern about the effects such a diversion would have on water quality in the Sacramento-San Joaquin Rivers and San Francisco Bay. Even without the canal Delta conditions are deteriorating. Some officials claim that the canal would solve the problem of reverse flow, but others caution against this view. Both recreational and commercial fishermen have long opposed the water projects that pose so great a menace to the important fish populations of the area. While much has been said about the long term effects of the canal, relatively little has been thought about the immediate effects. If conservation and wastewater reclamation would obviate the need for some facilities, it would seem difficult to justify the phenomenal expense of building the various facilities. The peripheral canal alone would cost about $1.3 billion by the time it would be completed. The costs of construction are only a beginning. It would take a tremendous and continual supply of electricity to transport water within California. (Baker-FRC)

Problems exist in management of water in the Volga River Basin, a heavily populated agricultural and industrial region of Russia. Large water losses occur in non-wet years (85-90% of the time) because water management below Volgograd has not been changed to meet the conditions produced by the controlled management above Volgograd. Conflicts in consumer demand are especially apparent in spring and in dry years. The hydropower, water transport, and irrigation interests favor storage of water in spring, with subsequent release during the year. The fishery and agricultural consumers in the lower reaches prefer a more unregulated flow. The planned water management programs designed to operate under conditions of controlled spring flood have been tried in the lower Volga reaches since 1959. Since it is difficult to forecast the optimal release, desired results are rarely achieved. The level of the Caspian Sea has been dropping and the water quality deteriorating. The spring releases also cause electric power production losses at the lower river hydrostations during the second quarter. These problems will become more serious and complex as water consumption in the region increases and the planned diversions to the Don and Ural Rivers are accomplished. Measures to alleviate the problems and reduce waste include development of intensive irrigated agriculture and controlled fisheries, improvement in techniques for forecasting river flow and economic effects, creation of better models to determine procedures for automatic control of reservoirs, and construction of a water distributor at the apex of the delta to sustain the flow in the Volga tributary (Buzan) at an acceptable level and lengthen the flood period for fish reproduction. Research was focused on the conflicting goals of land use expansion and the control of urban runoff effluent quality. A probablity distribution approach was used to obtain the distribution of the overflows and of pollutant concentration levels in the receiving stream. At the planning level, this approach is simpler than the simulation approach developed in previous research. This study also extends the theory of milti-criteria decision-making; (MCDM); the application of which to West Lafayette shows it to be a viable tool which deserves further study. The nearly-developed probability distributions provide a simple but powerful methodology for solving urban stormwater problems in estimating the size of the required detention storage, the reliability of the treatment system, and the size of the treatment plant for a given reliability level. The general MCDM prob-

LIBRARY U. OF I., URBANA-CHAMPAIGN

lem theory was extended by development of a new cutting plane algorithm. The probability distribution for the receiving stream pollutant concentration requires further research. Study of the potential for developing joint distributions for different hydrologic variables is also recommended. (Zielinski-MAXIMA)

EVALUATION OF SNOWMELT FORECASTING METHODS,
Washington Univ., Seattle. Dept. of Civil Engineering.
D. P. Lettenmaier, K. A. Erickson, and D. B. Parkinson.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-236662, Price codes: A05 in paper copy, A01 in microfiche. Technical Report No 68, December, 1980. 70 p. 11 Fig, 12 Tab, 20 Ref. OWRT A-104-WASH(1), 14-34-001-0151.

Descriptors: *Snowmelt, *Runoff forecasting, *Model studies, *Model testing, Thaw, Runoff volume, Runoff rates, Flood forecasting, Prediction, Projections, Water storage, Watershed models, Converter models, Hydrologic models, Statistical models, Evaluation analysis, Mathematical studies, Watersheds, Weather forecasting.

Snowmelt runoff forecast accuracy has significant economic implications for water resources management (especially for hydroenergy production and agricultural irrigation). Assessment of snowmelt forecasting methods was conducted as part of an on-going study of streamflow forecasting methods. Retrospective forecasts were made for two western Washington rivers using the National Weather Service snowmelt and soil moisture as state-of-the-art conceptual models (CMs), and the Tangborn hydrometeorological model as representative of the more sophisticated of the storage index (SI) models. Analysis of about 20 years of forecast data for both river basins indicated the CMs performed no better than the SI model, despite greatly increased logistical requirements. Analysis of four years of extreme low runoff data also showed no conclusive differences in forecast accuracy between the CMs and the SI model. Calculations made to determine the limiting forecast accuracy for the CM (conditions on the statistics of monthly simulation errors) showed that simulation error (largely dependent on data network density) probably limits forecast accuracy, especially for late runoff season forecasting; this implies that significant forecast accuracy improvements for CMs may not be possible, given current data limitations for many mountainous watersheds. Two situations are identified in which CMs are preferred over the SI model. (Zielinski-MAXIMA)

MODIFICATIONS TO STEAM CHANNELS IN THE BRISBANE METROPOLITAN AREA, AUSTRALIA,
Griffith Univ., Nathan (Australia). School of Australian Environmental Studies.
W. C. Boughton, and R. J. Neller.
Environmental Conservation, Vol 8, No 4, p 299-306, Winter, 1981. 5 Fig, 4 Tab, 23 Ref.

Descriptors: *Water management, *Environmental effects, *Urban runoff, Streamflow, Channel improvement, Channel morphology, Brisbane, Australia, Urban watersheds, Flood control, Urban drainage, Dams, Water supply, Runoff, Highways, Dredging.

The environmental impacts of human activities (urban development, water resources development, and dredging) in Brisbane, Australia, at the mouth of the Brisbane River are documented. One steam, the Big Creek, formerly used as the city's principal water supply, now flows through pipes under the central city; no traces of its course are visible on the surface. Several dams in the Brisbane watershed have affected the geomorpholgical characteristics of the streams by trapping sediment and reducing flows. Flood control works such as channel dredging and straightening now aid in carring stormwater runoff. Freeway construction has resulted in eliminating some creeks and digging new channels. Flood storage capacity in the Norman Creek valley has been reduced. Culverts and man made channels in the Freeway area have completely changed the characteristics of the stream channel. Enlargement of Brisbane Airport will cover Serpentine Creek, requiring construction of a new floodway. Sand, gravel, and other building materials have been dredged from streams for many years forming, in some cases, man made lakes. Sediment is trapped in these lake areas, causing degradation downstream. In other places sediment concentrations in water are greatly increased by excavation of clay and sand. Suburban development has affected characterisics of the streams by increased runoff from impervious areas and by increased flow velocity in artificial channels. (Cassar-FRC)

ISSUES IN SIMULATION MODEL DESIGN--A CASE STUDY,
Waterloo Univ., (Ontario). Dept. of Civil Engineering.
E. A. McBean.
Journal of Hydrology, Vol 51, No 1-4, p 205-218, May, 1981. 2 Fig, 3 Tab, 17 Ref.

Descriptors: *Simulation analysis, *Model studies, Mathematical models, Water resources development, Planning, Reservoirs, Irrigation, Hydroelectric power, Water transfer, Computers, *Argentina, Rio Colorado(Argentina).

Computer simulation of potential river basin development, until recently merely an interesting academic exercise, is now a practical enginering procedure of increasing utility in water management. As a result of the limitations on accuracy and fidelity inherent in all-encompassing models, many modeling studies tend toward the use of a number of relatively limited mathematical models, each of which is restricted in the scope of questions which it addresses, while still useful for providing particular insights into the planning problem. The simulation model described in this paper was one of four models developed as part of a large basin-planning study of the reservoir capacities, irrigation areas, diversions and hydroelectric installations for the Rio Colorado, Argentina. A governing criterion in designing this simulation model was the ability to accept from and provide information to the other models used in the study. The computational and data efficiency of the model, the output characteristics of the model, and the maintenance of a general structure which would enhance the ease of use on other basin planning problems were also major concerns in designing the model. The model utilizes the following types of required input data: system definition, economic data, structural data, and hydrologic data. Efforts have been made in designing the model to minimize the disturbance of the data deck required for the investigation of minor changes to the system components. The model was successfully applied as input to a large planning study of the Rio Colorado basin. It is capable of solving problems of about 100 event points for a 50-year simulation, three seasons per year, for about $10.00. (Carroll-FRC)

MODIFIED STANDARD OPERATION RULES FOR RESERVOIRS,
Technische Hochschule, Aachen (Germany, F.R.). Hydropower Div.
F. G. Rohde, and K. Naparaxawong.
Journal of Hydrology, Vol 51, No 1-4, p 169-177, May, 981. 3 Fig, 1 Tab, 10 Ref.

Descriptors: *Operating policies, *Reservoir operatin, Standards, *Optimization, Planning, Mathematical studies, *Simulation analysis, *Reservoir releases, Reservoir storage.

The problem of optimal reservoir operation occurs both in the planning phase, when operational costs and benefits related to different system designs must be assessed, and in the production phase, for the development of real-time management policies for existing systems. In the planning phase, two principal rules are widely applied: the standard operation rule and linear decision rules, derived either by implicit or explicit stochastic optimization techniques. The modified standard operation rule, which controls not only the reservoir release, but also the reservoir storage, provides a further alternative. Rules of this type are most widely applied in real-time reservoir operation. A procedure for the derivation of modified standard rules which uses time-dependent upper and lower storage bounds determined by a two-stage optimization process is presented. The application of this technique to an existing two-reservoir system in Thailand, which produces hydroelectric power, irrigation water, and low-flow augmentation for salinity control, is discussed. Long term simulations were used to compare the derived rule with the rules presently used in real-time operation. These simulations showed that, although the difference in system output in absolute terms was small, the operation with the new rule resulted in the increase of firm energy, non-firm energy and dependable capacity and in the decrease of frequency and volume of reservoir spills. SOME CHARACTERISTICS AND IMPLICATIONS OF DRAINAGE BASIN LINEARITY AND NON-LINEARITY,
Nebraska Univ., Omaha. Dept. of Civil Engineering.
W. F. Rogers.
Journal of Hydrology, Vol 55, No 1/4, p 247-265, 1982. 2 Fig, 1 Tab, 3 Ref.

Descriptors: *Drainage engineering, *Runoff volume, *Linearity, Hydrologic models, *Rainfall-runoff relationships, Peak discharge, River basins, Precipitation, Design criteria, Unit hydrographs, Hydrographs.

In linear drainage basins runoff volume is directly proportional to precipitation volume, whereas in nonlinear drainage basins it is not. When the slope of the mathematical linear equation describing the

second-order standardized peak discharge distribution (SSPDD) is about -1.00, the drainage basins are linear. If the slope is less than -1.00, the drainage basin is nonlinear. The degree of nonlinearity is indicated by the magnitude of the negative slope of the SSPDD. The small- and medium-sized basins (up to 450 sq mi) studied had slopes from -1.02 to -2.83, mean -1.38. Using linear design procedures such as the unit hydrograph in nonlinear basins can result in serious overdesign. Peak discharge from Codorous Creek, Pennsylvania, drainage area 73.4 sq mi with a nonlinear slope of -1.39, was overestimated by 72% using linear equations. (Cassar-FRC)

LINEAR AND NONLINEAR RUNOFF FROM LARGE DRAINAGE BASINS,
Nebraska Univ. at Omaha. Dept. of Civil Engineering.
W. F. Rogers, and H. A. Zia.
Journal of Hydrology, Vol 55, No 1/4, p 267-278, 1982. 4 Fig, 1 Tab, 3 Ref.

Descriptors: *Drainage engineering, *Runoff volume, *Linearity, Snowmelt, Hydrologic models, Rainfall-runoff relationships, Peak discharge, Precipitation, Design criteria, Hydrographs, Unit hydrographs, River basins.

The second-order standardized peak discharge distribution (SSPDD) procedure described in a previous paper was applied to large drainage basins, 450 to 8190 sq mi. These basins showed linearity and nonlinearity with slopes of -1.01 to -1.43 derived from the equations. Even very small runoff volumes (0.001 inch expressed as depth distribution over the drainage basin) fit the distribution well. Twenty-two snowmelt hydrographs from several basins in Nebraska also fit the distribution. (Cassar-FRC)

KINEMATIC WAVE THEORY OF CATCHMENT RESPONSE WITH STORAGE,
Newcastle Univ. (Australia). Dept. of Civil Engineering and Surveying.
W. G. Field.
Journal of Hydrology, Vol 55, No 1/4, p 279-301, 1982. 9 Fig, 1 Tab, 11 Ref.

Descriptors: *Runoff, *Storage, *Kinematic wave theory, Rainfall-runoff relationships, Catchments, Excess rainfall, Open-channel flow, Hydrographs, Channel storage, Hydrologic models, Model studies, Urban runoff.

The catchment response model proposed in this paper consists of a continuous distribution of storage elements feeding into a branched channel system. It is assumed that rainfall excess enters the off-channel storage elements (linear or nonlinear) before being transformed to channel elements (linear or nonlinear) for transport to the catchment outlet. The discharge hydrograph is produced from solving the kinematic wave equation using the method of characteristics. Illustrations are given using a rectangular catchment and a linear catchment. It is shown that the model is a generalization of several other well-known models. For a linear catchment the runoff hydrograph is described by a double convolution integral in which the rainfall excess function and catchment time-area function can be interchanged to produce the solution for an equivalent catchment and hyetograph shape. Typical values for runoff coefficients are given for small rural catchments of different soil types and vegetation. For design purposes urban areas may be divided into impervious and pervious subareas. (Cassar-FRC)

FLOODPLAIN ANALYSIS, SIMPLIFIED VS. COMPLEX METHODS: A CASE STUDY,
Enviroscience, Inc., Minneapolis, MN.
I. Yomtovian, and D. Ford.
Water Resources Bulletin, Vol 18, No 2, p 259-263, April, 1982. 3 Fig, 1 Tab, 6 Ref.

Descriptors: *Flood plain management, *Flood insurance, *Flood profiles, Nonstructural alternatives, Flood damage, Flood discharge, Hydrologic models, Model studies, Maps.

Simple and complex methods of determining flood plain information were compared using data from three North Dakota creeks: Apple, Burnt, and Hay. A simplified manual technique (Soil Conservation Service) and a complex computer technique (HEC-2) produced similar flood plain boundaries. Differences of 1-3 ft in 100-year surface profiles were found in use of the 2 methods. Major differences were in locations near bridges. Simplified methods are recommended for rapid determination of flood hazard, flood information studies, and preparation of inundation maps for flood emergency plans. The complex mathematical models are recommended for determining the 10- and 100-year flood elevations. (Cassar-FRC)

RESOLVING THE FISH VS FLOOD CONTROL CONTROVERSY ON THE VEDDER RIVER,
E. Bonham.
Canadian Water Resources Journal, Vol 5, No 1, p 38-53, 1980. 1 Fig, 3 Ref.

Descriptors: *Flood control, *Fisheries, *Channel improvement, Vedder River, British Columbia, Flood plain management, Dikes, Dredging, Bank protection, Sedimentation, Gravel, River beds, Water management.

A destructive flood of the Vedder River, British Columbia, in December 1975 prompted immediate remedial work--repair of the existing bank protection, scalping of major bars, burning of wood debris (completed March 1976), and removal of 750,000 cu yards of gravel from the main channel in July-August 1976. A management plan was devised as a long-term solution to accommodate both flood protection against a 200-year event and the salmon and trout fisheries. Strategies include increasing the floodway width and construction of 10 ft high gravel setback dikes, provision of ten 8' x 8' culverts in the railway embankment near the B. C. Hydro bridge constriction, and floodboxes within the setback dikes to enhance fish spawning. Cost estimates for the project, expected to be finished in 1982, are $1.8 million. The Vedder River Management Committee was formed in April 1980 with representatives in flood control, fisheries, wildlife, recreation, and agriculture. Major activities of the Committee will be to accommodate the conflicting interests, devise a long-term river sedimentation and gravel removal program, administer leasing of flood plain land for grazing and haying, and establish a riverside campsite. THE MACKENZIE RIVER BASIN STUDY,
Saskatchewan Dept. of the Environment, Regina. Inland Waters Directorate.
H. Foerstel.
Canadian Water Resources Journal, Vol 5, No 2, p 13-27, 1980. 4 Fig, 4 Ref.

Descriptors: *Canada, *Water management, *Data collections, *Mackenzie River, History, Network design, River basins, Slave River, Deltas, Floods, Planning, Water policy.

The 3-year Mackenzie River Basin study, scheduled for completion in August 1981, covers a vast area (one-fifth of Canada) for which little data has been compiled. The study's main objective is to plug the many gaps in information. Because of the remoteness and enormous size, severe weather, and torrential flows in spring, information was scarce on precipitation in the mountains, the weather, water quality, the Slave River Delta, the Liard River spring ice breakup, the interrelations in the alluvial ecosystem, and the Athabasca Sand Dunes. All these fields have been under study. Some of the difficulties encountered in this basin study are the vast size (which required consideration of scales varying from very local to almost continental), the enormous but still inadequate amount of data, the verbosity of reports, long distance effects, and multiple interests. WATER FLUCTUATION AND THE AQUATIC FLORA OF LAKE MICCOSUKEE,
Florida Dept. of Natural Resources, Tallahassee Bureau of Aquatic Plant Research and Control.
D. P. Tarver.
Journal of Aquatic Plant Management, Vol 18, 19-23, 1980. 1 Fig, 3 Tab, 12 Ref.

Descriptors: *Water level fluctuations, *Aquatic plants, *Weed control, Lakes, Lake Miccosukee, Florida, Aquatic weeds, Drawdown, Vegetation, Sediments, Lake sediments, Organic matter, Plant populations, Aquatic weed control.

In an attempt to control aquatic plant growth Lake Miccosukee, Florida, a shallow 2954 ha lake, was drawn down 1.7 m, so that by September 1977 90% of the lake bottom was exposed to drying conditions. Water level returned to normal by April 1978. Total water surface coverage in summer was 81% before drawdown (June 1976)

LIBRARY U. OF I., URBANA-CHAMPAIGN

and 75.6% after drawdown and refilling (June 1978); in winter 62% before drawdown (February 1977) and 26% after drawdown and refilling (February 1979). Some plant species were considerably reduced as a result of drawdown: water shield, cabomba, variable leaf milfoil, water willow and related plants, and bladderwort. Several other plant types increased in abundance or remained at constant levels: azolla, duckweed, bog mat, frog's bit, yellow cow lily, fragrant water lily, and terrestrial annuals. Drying and plant desiccation produced compaction and stabilization of sediments. The peat zone decreased 70% in depth (from 6-40 cm to 3-12 cm) and the muck zone, 17% (from 3-40 cm to 3-39 cm). HYDROLOGIC RECONNAISSANCE OF THE NOATAK RIVER BASIN, ALASKA, 1978,
Geological Survey, Anchorage, AK. Water Resources Div.
J. M. Childers, and D. R. Kernodle.
Geological Survey Open-File Report 81-1005 (WRI), 1981. 38 p, 18 Fig, 8 Tab, 10 Ref.

Descriptors: *Hydrologic data, *Surface water, *Springs, *Streamflow, Flow rates, Discharge measurement, Floods, Flood peak, Runoff, High water mark, Ice, Bank erosion, Aquatic life, Invertebrates, *Alaska, Noatak River basin, Arctic.

Hydrologic data were collected in 1978 described water resources of the Noatak River basin, Alaska. Streamflow varies seasonally. No flow was observed from the upper part of the basin in late winter (April). In the lower part of the basin springs support perennial flow in the Kugururok River and downstream along the Noatak. The discharge of the Noatak was 150 cubic feet per second in April 1978. During the summer, rainstorms are common, and runoff produces high flow. During August 1978, flow was normal in the basin; unit runoff averaged about 1 cubic foot per second per square mile. The Noatak is a gravel-bed stream of moderate slope. It drops about 1,800 feet in elevation from a point near the head waters to the mouth, a distance of 400 miles. Streambed material in most places is gravel, cobbles, and boulders, maximum riffle depths and pool widths increase in a downstream direction. Stream velocity in August 1978 increased from about 1 foot per second in the upper basin to about 4 feet per second in the lower reaches. High-water marks of the maximum evident flood were found at elevations from bankfull to 5 feet above bankfull. Maximum evident flood unit runoff rates were estimated to be less than 50 cubic feet per second per square mile. Scars produced by ice jams were seldom seen above bankfull. Bank erosion appears to be most active in the lowlands. Water in the Noatak River basin is virtually unaffected by man's activity. Water quality varies with location, weather, season, and source; the water is normally clear, cool, and hard. During late winter sea water intrudes into the Lower Noatak Canyon. Benthic invertebrate community composition and variability suggest the river's undiminished natural quality. (USGS)

COLORADO RIVER DEVELOPMENT,
Colorado State Univ., Fort Collins. Dept. of Agricultural and Chemical Engineering.
G. V. Skogerboe.
Water Supply and Management, and Management, Vol 6, No 1-2, p 29-61, 1982. 10 Fig, 1 Ref.

Descriptors: *Water resources development, *Colorado River, *Resources development, *Reclaimed water, *Project planning, Water supply development, River basins, Water use, Water management, Irrigation water, Water supply.

Since the enactment of the Reclamation Act of 1902, many attempts have been made to develop the water resources of the Colorado River Basin. Some early reclamation projects which played a major role in the development of the western United States are reviewed. Many newer projects including the Central Utah Project and the Central Arizona Project are currently under construction. The Central Utah Project will develop water from Utah Lake, the Provo River, and water tributary to the Colorado River for use in the Uinta Basin and the eastern part of the Bonneville Basin. The Central Arizona Project will provide supplemental Colorado River water to nearly 1 million acres of agricultural land in several Arizona and New Mexico counties and municipal and industrial water for the Phoenix and Tucson metropolitan areas. Additional projects have been authorized but are not yet under construction. The present storage capacity of the Colorado River Basin exceeds 65 million acre-feet, which is more than four times greater than the rivers' mean annual flow. Billions of dollars have already been spend for developing this river basin. (Geiger-FRC)

BARRIERS TO EFFECTIVE GROUND-WATER MANAGEMENT: THE CALIFORNIA CASE,
California Univ., Riverside. Dept. of Soil and Environmental Sciences.
K. Knapp, and H. J. Vaux, Jr.
Ground Water, Vol 20, No 1, p 61-66, 1982. 3 Tab, 11 Ref.

Descriptors: *California, *Groundwater management, *Model studies, *Cost analysis, *Groundwater mining, Groundwater depletion, Water demand, Water supply, Water supply development, Water management, Water law, Water policy, Pumping, Available water.

In California, 40% of the annual water needs are met by groundwater which is essentially unmanaged. As surface supplies become scarcer, groundwater depletion becomes more of a concern. A dynamic optimization model was used to show that substantial benefits may be gained from groundwater management in the southern San Joaquin area. The magnitude of these benefits is influenced by energy costs, interest rates, water demand and the availability of substitute surface supplies. The regulatory strategy chosen for management will affect the distribution of benefits. If additional surface water supplies are provided, groundwater mining is permitted even where quality is threatened. Individual fears of economic loss suffered for the collective and uncertain gain to a larger group are a real barrier to the implementation of groundwater management programs. In order to be effective, future groundwater management policies in California will have to be uncomplicated, equitable, flexible, and inexpensive to administer. (Geiger-FRC)

THE POTENTIAL FOR GROUND-WATER MANAGEMENT IN THE WEST: A SYMPOSIUM,
Oklahoma State Univ., Stillwater.
J. W. Westphal.
Ground Water, Vol 20, No 1, p 59-60, 1982. 3 Ref.

Descriptors: *Groundwater management, *Symposium, *Water supply development, *Water policy, *Water table decline, Environmental policy, Groundwater mining, Water resources development, Water rights, Water law, Irrigation water, Aquifers, *Western United States.

Many states in the West have no clear policy on groundwater use. Since a user's rights involve a combination of physical, economic, and social factors, competition among these interests should be expected. About 80% of the total irrigation in the United States takes place in 17 western states. Groundwater in the West constitutes 46% of its domestic use and 44% of its industrial use. This heavy use has resulted in decreasing water tables, especially in the Ogallala aquifer. The depletion of groundwater has caused a decline in streamflow. There seems to be room for careful development and management of groundwater resources in the West without totally exhausting the supply. California and Texas have virtually no groundwater rights law and only New Mexico had water quality standards for groundwater. Oklahoma is the only Western state with an existing comprehensive groundwater law. Five groundwater management studies are presented in a symposium to identify some management issues and see how they relate to economic and social considerations. They cover such topics as groundwater management in California, Arizona and the High Plains area, the Ogallala aquifer, surface water-groundwater interrelationships, and the storage and transmission characteristics of the basalts of the Pacific Northwest. (Geiger-FRC)

GROUND-WATER NETWORK DESIGN FOR NORTHWEST KANSAS, USING THE THEORY OF REGIONALIZED VARIABLES,
Kansas State Geological Survey, Lawrence.
M. Sophocleous, J. E. Paschetto, and R. A. Olea.
Ground Water, Vol 20, No 1, p 48-58, 1982. 14 Fig, 7 Ref.

Descriptors: *Groundwater management, *Networks, *Observation wells, *Water table decline, *Kansas, *Statistical methods, Network design, Water table wells, Monitoring, Test wells, Water table fluctuations, Water surface profiles, Groundwater depletion, Aquifers, Error analysis.

A study of the existing groundwater observation well network in northwest Kansas was designed to formulate the most effective arrangement for evaluating water table levels and monitoring groundwater resources. The theory of rationalized variables was used to estimate the amount of spatial variability of the water table surface. Structural analysis, a statistical procedure that investigates the behavior of a mapped variables with changes in distance, was employed. Semivariograms were used to assess the degree of spatial continuity of the water table. The method was applied to Groundwater Management District No. 4, which holds groundwaters mainly of the Ogallala Formation. The error analysis produced by universal kriging showed that fewer wells would be required for the same level of accuracy if a regular 5.4-km network was used. Reducing the estimation error in the water-table surface uniformly throughout the region proved impractical due to the higher costs of well monitoring. (Geiger-FRC)

ECONOMICS OF DECLINING WATER SUPPLIES IN THE OGALLALA AQUIFER,
Oklahoma State Univ., Stillwater. Dept. of Agricultural Economics.
J. Warren, H. Mapp, D. Ray, D. Kletke, and C. Wang.
Ground Water, Vol 20, No 1, p 73-79, 1982. 4 Fig, 1 Tab, 8 Ref.

Descriptors: *Groundwater management, *Oklahoma, *Model studies, *Groundwater depletion, *Economic aspects, *Irrigation requirements, *Computer models, Aquifers, Crop production, Agriculture, Cultivated lands, Irrigation effects, Irrigation water, Irrigation wells, Water demand, Water supply, Water supply development, *Ogallala aquifer.

Discovery and exploitation of the Ogallala Formation generated dramatic economic growth, primarily based on irrigated agriculture, in the High Plains region of the United States beginning early in the twentieth century. The problem of declining water levels in the Ogallala Aquifer began to attract public attention in the early 1970s. An integrated six-state study was initiated, in which Oklahoma researchers developed a computer model of the agricultural sector of northwestern Oklahoma and estimated irrigated and dryland cropping patterns, farm output and farm income over a 40-year

planning horizon. Sensitivities of the outputs to alternative assumptions on energy costs, commodity prices and technological development were also analyzed. The model was run for a baeline case and two water management alternatives. Preliminary results suggest a favorable outlook for irrigated agriculture in the area through the near to mid term. GROUND-WATER MANAGEMENT IN BASALTS,
California Univ., Davis. Dept. of Geograaphy.
M. L. Shelton.
Ground Water, Vol 20, No 1, p 86-93, 1982. 4 Fig, 18 Ref.

Descriptors: *Groundwater management, *Model studies, *Groundwater storage, *Basalts, *Water management, *Groundwater basins, Aquifers, Groundwater recharge, Groundwater mining, Groundwater depletion, Water resources development, Decision making, Hydrologic models, *Columbia River basalts.

The mining of groundwater in the Columbia River basalts of the Pacific Northwest is complicated by the spatial variability of the hydrologic properties of the deep stratified lava flows. This area is experiencing greater demands for groundwater resources due to new irrigation projects and municipal and industrial requirements. Individual basin studies aid in decision making on water management issues and also increase the data on regional groundwater systems. The Deschutes River Basin system in Oregon is described by a distributed-system multiple storage model which gives the magnitude of spatial variations in groundwater recharge, storage, and discharge for this watershed. The functional properties of the basin groundwater system and the presence and magnitude of its interbasin linkages are revealed by input-output analysis. Model simulations of storage and transmission characteristics suggest that basin or regional perspectives are required to fully utilize the groundwater stored in basalts. (Geiger-FRC)

GROUND-WATER DEVELOPMENT IN WESTERN RIVER BASINS: LARGE ECONOMIC GAINS WITH UNSEEN COSTS,
Arizona Univ., Tucson. Dept. of Agricultural Economics.
J. T. Daubert, and R. A. Young.
Ground Water, Vol 20, No 1, p 80-85, 1982. 2 Tab, 14 Ref.

Descriptors: *Groundwater management, *Colorado, Surface water availabilty, *Economic aspects, *Water rights, *Computer models, *Water supply development, Model studies, Groundwater depletion, Water shortage, Water law, Simulation analysis, Digital computers, Irrigation water, Aquifers, Water demand, Water management, Groundwater availability.

In river basins where aquifers are in close hydrologic contact with streams, groundwater development projects can lower water tables and decrease the amount of surface water available for irrigation of cropland. A digital computer simulation model was formulated to study the economic impact of water management policies in the lower South Platte River basin of Colorado. Colorado water law gives priority on appropriation of water to senior water rights holders with the earliest application dates. Those with subsequent dates hold junior rights. Evaluations of an independent water allocation approach showed that surface water owners cannot protect their historical water rights and must cope with costs associated with declining surface diversions. An approach which allocated both surface and groundwater according to prior appropriation protects senior surface water rights, forcing groundwater users to cease pumping or pay full damages. An open access management policy yielded high income benefits but imposed greater costs on the users of surface water when water supply shortages occurred. Regulation of groundwater usage under the appropriation system reduced the losses of surface water users, but greatly reduced the profits of groundwater users. (Geiger-FRC)

Available from the National Technical Information Service, Springfield, VA 22161 as PB82-220625, Price codes: A04 in paper copy, A01 in microfiche. Report, March 1982. 53 p, 6 Fig, 16 Ref, 2 Append. B-091-NY(1). 14-34-0001-9087.

Descriptors: Sewerage network, Optimization, Groundwater, 201 regions, Urbanization, *Model studies, *Sewer systems, *Wastewater facilities, Groundwater recharge, Water pollution control, *Groundwater management, *Suffolk County, Long Island, *New York.

Augmentation of a network of sewer lines and wastewater treatment plants is anlayzed using optimization methods. The optimization model uses integer programming to determine the most economical location of wastewater treatment plants and sewer pipe routes. Because of the extraordinarily large number of integer variables, a special procedure was developed to solve the integer programming problem. The optimization model was applied to western Suffolk County in Long Island, N.Y. The patterns of wastewater treatment and collection which the optimization program found to be least expensive were also those which had relatively little recharge of treatment plant effluent to groundwater. Because of concerns that such major changes in recharge patterns would result in decreased streamflows, the optimization model was modified to encourage more recharge to groundwater. Similarly, preferences for preserving 201 boundaries in wastewater treatment and collection were addressed by computing the solution to the optimization model with restrictions which prevented shipment of wastewater from 201 region to another. The results indicated that the cost for wastewater treatment could be as much as $100 M (18%) more expensive if western Suffolk County is forced to consider only local treatment within existing 201 areas instead of more efficient regional alternatives.

REFLECTIONS OF THE CHOICE OF SOME PRIORITY AXES OF HYDRAULIC RESEARCH IN THE FIELD OF LAND AND WATER MANAGEMENT,
Rural Department for Waters and Forestry, Paris (France).
R. Darves-Bornoz.
Journal of Hydraulic Research, Vol 19, No 4, p 307-315, 1981.

Descriptors: *Hydraulics, *Agriculture, Agricultural engineering, Irrigation, Water reuse, Water use efficiency, *Water management, *Land management, Drainage, Irrigation efficiency, Priorities.

Priorities for hydraulic research in the area of land and water management are discussed. Agricultural hydraulics plays a major role in how problems relating to global food production and water management are addressed. The saving of water in irrigation and the increased efficiency of its use for crop production are at the core of major world problems. Reuse of wastewaters for agricultural purposes is another area requiring further investigation. International objectives relating to agricultural and rural development in developing countries are partly linked to water control in agriculture. A better knowledge of the terrestrial cycle of water is needed. Water retention in soil for rainfed agriculture, reduction of irrigation water losses, drainage of excess water, and control of recharge to underground waters are the modifying actions of terrestrial cycle of water at the quantity level which need to be addressed by hydraulic research. Means for avoiding salinization of soils and water and pollution of underground water resources and rivers need to be developed to help improve or maintain the quality of water in this cycle. There is a need for a generalized physico-mathematical model of the terrestrial cycle which will permit consideration of the impact of all human actions on the quality and quantity of water. The relationship between irrigation and power resources also needs to be investigated. (Carroll-FRC)

Available from the National Technical Information Service, Springfield, VA 22161 as PB82-236605, Price codes: A03 in paper copy, A01 in microfiche. Technical Memorandum Report No 63, March, 1981. 38 p, 2 Fig, 4 Tab, 1 Ref, 1 Append. OWRT A-082-HI(1), 14-34-0001-0113.

Descriptors: *Groundwater availability, *Aquifers, *Pump wells, *Water level fluctuations, *Water resources development, Groundwater depletion, Groundwater management, Groundwater recharge, Groundwater storage, Electrical conductivity, Salinity, Water use, Water management, Available water, Water supply.

A detailed 2.5 year study was carried out to assess the magnitude and fluctuation of fresh groundwater resources of Kwajalein Island. Twenty-three observation wells were constructed and monitored with respect to the thickness, areal-extent, and quality of the groundwater lens. Recharge to the fresh groundwater lens averaged 1,140,000 cu m/year (300 million gallons/year (MG/Y)) over the study period, ranging from 893,000-1,450,000 cu m/year (236-383 MG/Y). The average fresh groundwater lens storage was over 1,060,000 cu m (280 million gallons), but fluctuated widely from about 908,000-1,210,000 cu m/year (50 MG/Y) for safe extraction, provided that an additional lens well is constructed. It is recommended that a proposed new pumping code be instituted on a trial basis to better utilize catchment during the wet season, and storm recharge to the groundwater lens during the dry season. In addition, the present salinity monitoring program (electrical conductivity observations) should be continued to permit assessment of any lens changes which might occur from groundwater development from the proposed new lens well. EFFICIENT WATER USE IN CALIFORNIA: CONJUNCTIVE MANAGEMENT OF GROUND AND SURFACE RESERVOIRS,
Rand Corp., Santa Monica, CA.
D. J. Jaquette.
Journal of Hydrology, Vol 51, No. 1-4, p 187-204, May, 1981. 4 Fig, 9 Tab, 16 Ref.

LIBRARY U. of I., URBANA-CHAMPAIGN

Descriptors: *Groundwater management, *Water use efficiency, *Water supply development, Groundwater reservoirs, Reservoir operation, Water policy, Water management(Applied), Surface water, *California, *Conjunctive use.

This paper presents a summary of the findings of the Rand Corporation's study of water use efficiency in California. The study, which produced a wide variety of policy recommendations designed to improve the efficiency of water use in the State, found that an integrated water management plan could result in the development of significant quantities of new water at costs considerably less than the costs of new water from major facilities proposed for the State. The report recommended an aggressive plan for the conjunctive management of surface and groundwater reservoirs. This conjunctive use plan calls for releases in excess of customer needs to be made from the surface reservoirs and delivered to water contractors for groundwater recharge through the flooding of spreading grounds or through surface deliveries to current pumpers. Water shortages would be met by repumping water from the ground. Analysis of the feasibility of this plan showed that conjunctive management is most profitable in areas with high groundwater tables and in river systems with high ratios of average inflow to reservoir storage capacity; that more aggressive conjunctive management can result in the development of significant amounts of new water, perhaps delaying the need for new facilities; that conjunctive management plans benefit significantly from even modest advances in the reliability of long-range weather forecasting; and that conjunctive use is economically viable and physically feasible. It is suggested that the benefits of conjunctive use are attractive enough that the State should direct attention to overcoming the political and institutional barriers to such a management plan. DEEP DRAINAGE AND WATER USE OF FORESTS AND PASTURES GROWN ON DEEP SANDS IN A MEDITERRANEAN ENVIRONMENT,
Alcoa of Australia, Pinjarra.
B. A. Carbon, F. J. Roberts, P. Farrington, and J. D. Beresford.
Journal of Hydrology, Vol 55, No 1/4, p 53-63, 1982. 5 Fig, 4 Tab, 14 Ref.

Descriptors: *Soil-water-plant relationships, *Recharge, Groundwater recharge, Evapotranspiration, Pastures, Sands, Forests, *Australia, *Neutron activation analysis.

Soil water content was determined beneath three different types of vegetation growing in deep sands of southwestern Western Australia for the purpose of studying deep drainage and aquifer recharge. The climate in this region is Mediterranean (cool, rainy winters and hot, dry summers). The neutron scattering method was used for field measurements in native hardwood forests, softwood plantations, perennial pastures, and winter annual pastures. Results indicated that deep drainage was greatest under winter annual pastures and least under Pinus pinaster (Ait.) plantations. Perennial pastures and native forests were similar in water use patterns, soil water depletion and deep drainage, contributing about 34% of the annual water balance to deep drainage. Thus replacing natural forest with pine plantations would decrease groundwater recharge, while replacing with annual pasture would increase recharge. (Cassar-FRC)

CHEMICAL CONSTRAINTS OF GROUNDWATER MANAGEMENT IN THE YUCATAN PENINSULA, MEXICO,
Geological Survey, Reston, VA.
W. Back, and J. M. Lesser.
Journal of Hydrology, Vol 51, No 1-4, p 119-130, May, 1981. 25 Ref.

Descriptors: *Water management(applied), *Groundwater management, Chemical properties, History, Geologic formations, Geohydrology, Groundwater pollution, *Geochemistry, Limestone, Solubility, Karst, Salinity, *Mexico(Yucatan Peninsula), Aquifer management.

Throughout its history, the cultural and economic development of the Yucatan Peninsula in Mexico has been significantly affected by the management of water resources. At present, the two critical objectives for groundwater management in the Yucatan are the development of regional groundwater supplies to meet the increasing demands of the expanding populations and the growing tourist industry in the area and the control of groundwater pollution in this chemically sensitive system made critically vulnerable by climate and geologic conditions. The chemical character of the groundwater of the Yucatan is largely controlled by the mixing of rain water with the sub-surface salt water, the solution of limestone and gypsum, and contamination by organic material and sewage. Although the peninsula is a coastal plain underlain by permeable limestone and has an annual rainfall of over 1,000 millimeters, which should provide abundant supplies of water, factors of climate and hydrogeology have combined to form a hydrologic system in which fresh water is scarce and whose chemical environment further decreases that restricted supply. Many wells have recently had to be abandoned due to serious pollution problems resulting from the use of sewage disposal wells adjacent to supply wells. The Secretaria de Recursos Hidraulicos has been charged with responsibility for scientific investigations and development programs for water supply and sewage disposal systems for the region since 1959. Several studies have been undertaken, water supply problems have been resolved so that cities and towns generally have safe water supplies, and sewage treatment and disposal programs are being developed. THE LIKELIHOOD OF ACTIVE GROUNDWATER RECHARGE IN THE BOTSWANA KALAHARI,
Institute of Geological Sciences, Wallingford (England). (United Kingdom).
S. S. D. Foster, A. H. Bath, J. L. Farr, and W. J. Lewis.
Journal of Hydrology, Vol 55, No 1/4, p 113-136, 1982. 10 Fig, 2 Tab, 28 Ref.

Descriptors: *Groundwater recharge, *Infiltration, *Excess rainfall, Recharge, Kalahari Desert, Africa, *Botswana, Kweneng, *Sands, Groundwater mining, Geohydrology, Pore water, Rainfall, Evaporation, Dating, Groundwater, Semiarid lands.

Groundwater resources were investigated in the Kalahari, covering over 2.5 million sq km of southern Africa with surface sands up to 9 m deep. This region is virtually devoid of surface water. Samples of soil and rock were collected by drilling to determine the geological and physical properties and the chemical and isotopic character of the interstitial water. Evidence indicates that in the study region, the Kweneng, which has a mean annual rainfall of 450 mm, diffused groundwater recharge is unlikely where sand cover is more than 4 m deep. Any short term excess rainfall is stored in the sands and used by vegetation or evaporated. Tritium and radiocarbon analysis of the groundwater being used in this area indicated ages of 2000-4500 years for some samples and over 10,000 years for others. These correspond with the two most recent pluvial eposides in the Kalahari, 750-2500 and 13,000-18,000 years ago. Therefore, it must be assumed that groundwater wells in this area are tapping unreplenishable supplies, unless the presence of deep aquifers and sand-free tracts can be confirmed. (Cassar-FRC)

POTENTIAL FOR GROUNDWATER RECHARGE SEEPAGE FROM FLOOD-RETARDING RESERVOIRS IN SOUTH CENTRAL NEBRASKA,
Nebraska Univ.-Lincoln. Dept. of Agricultural Engineering.
D. E. Eisenhauer, D. M. Manbeck, and T. H. Stork.
Journal of Soil and Water Conservation, Vol 37, No 1, p 57-60, January/February, 1982. 2 Fig, 3 Tab, 16 Ref.

Descriptors: *Groundwater recharge, *Reservoirs, *Seepage, Recharge, *Nebraska, Big Blue River Basin, Runoff, Irrigation, Hydrologic budget, Aquifers, Water conservation.

Seepage rates at two flood control reservoirs in Nebraska's Upper Blue River Basin were monitored April through November 1975-77 to determine their contribution to groundwater recharge. Average seepage rates for the 1000 acre reservoirs were 0.50 inch per day and 0.59 inch per day at the Clay County site and the York County site, respectively. Average annual seepage volumes were 53 acre-feet at the Clay site and 92 acre-feet at the York site. Although the sum of the volume of outflow and seepage was nearly equal for both sites, about 130 acre-feet per year, the York County reservoir was more conducive to seepage because its surface area at high water levels was greater. It is possible to use reservoirs for groundwater recharge in the Great Plains, but the method is less feasible west of the study area. In the more arid regions there is less surface water and evaporation rates are higher, requiring more efficient recharge systems. (Cassar-FRC)

WATER-LEVEL FLUCTUATIONS DUE TO EARTH TIDES AT FORT MACKAY, ALBERTA,
Northern Illinois Univ., DeKalb. Dept. of Geology.
D. A. Hackbarth.
Canadian Water Resources Journal, Vol 5, No 1, p 87-99, 1980. 2 Fig, 2 Tab, 15 Ref.

Descriptors: *Tidal effects, *Water level fluctuations, *Well hydraulics, Groundwater movement, Fort MacKay, Alberta, Confined aquifers, Aquifers, Gravity waves, Statistical analysis, Tides, Hydraulics, Geohydrology.

Diurnal water level fluctuations were observed in a 315 m deep well, stratigraphically the lowest in a network of 90 wells in the Athabasca Oil Sands area. The well is completed fractured Devonian rocks. Overlying and underlying the water source are rocks of low permeability. The pressure head is well above the top of the aquifer. Statistical analysis indicated that barometric pressure was not a factor. However, autocorrelation of tidal-gravity corrections and water level fluctuations showed periods of 24.2 and 24.7 hours, respectively. Cross-correlation of residual water level and total gravity showed a period of 24.2 hours. Ratios of the wave amplitudes of tidal-gravity corrections and residual water levels were essentially constant. A semidiurnal wave did not appear to be present. In this well a 6-hour time lag was observed. This was caused by the slow response of the water to pressure changes in the aquifer and by the high total dissolved solids levels, 240,000 mg ep per liter. All evidence confirmed that the water level fluctuations were a result of earth tides. (Cassar-FRC)

THE HYDROGEOLOGICAL BASIS FOR A WATER SUPPLY TO KABWE, ZAMBIA,
Aspinwall Hydrotechnical Services Ltd. (England), (United Kingdom).
J. F. T. Houston, and M. J. Morrey.
Journal of the Institution of Water Engineers and Scientists, Vol 36, No 1, p 27-42, 1982. 10 Fig, 2 Tab, 8 Ref.

Descriptors: *Hydrogeology, *Aquifer characteristics, *Groundwater mining, Water quality, Well yield, Water supply, Kabwe, *Zambia, Drilling, Groundwater recharge, Recharge, Groundwater availability, Groundwater budget, Groundwater management.

Results of a feasibility study for groundwater exploitation of the Dolomite Aquifer near Kabwe, Zambia, are reported. The investigation involved exploration, drilling, pump testing, and ancillary studies. The exploration phase used aerial photographs and resistivity depth soundings. In the drilling phase three types of boreholes were used: two NX-sized cored boreholes of 150 m depth to quantify fissure frequency and to locate the aquifer base and 21 150 mm percussive rotary boreholes to define the aquifer's extent and to find sites for the seven 300 mm rotary test production boreholes. Pumping tests were undertaken on the 150 mm boreholes, and the test production boreholes were tested with a turbine pump. Other tests included electric and gamma logs, fluid conductivity and temperature logs, and groundwater analysis. The aquifer base is about 80 m deep, and the dolomite formation 150 m. Transmissivity values are 200-500 sq m per day in the northeast, more than 1000 sq m per day over most of the aquifer, and up to 3500 sq m per day in areas of localized fissure development. Specific yield is 0.14 on the average. Waters are dominated by Ca-Mg-carbonate-bicarbonate ions and have 500 mg per liter total dissolved solids. The upper 20 m section of the dolomite has lower conductivity than the deeper layer. Annual precipitation recharge during 1965-80 was 26-771 mm in short vegetation areas and 0-534 mm in open forest. Subsurface recharge from the surrounding schist varies between 500 and 1200 cu m per day per km of boundary. Current demands on the Dolomite Aquifer are 55 Ml per day, total annual recharge 50-70 Ml per day. Recommendations for best development of the well field include new boreholes to spread abstraction over a wider area and to reduce the present pumping from the Kalulu well field. (Cassar-FRC)

ANNUAL SUMMARY OF GROUND-WATER CONDITIONS IN ARIZONA, SPRING 1979 TO SPRING 1980.
Geological Survey, Tucson, AZ. Water Resources Div.
Geological Survey Open-File Report 81-906 (WRI), July 1981. 2 Plates, 25 Ref.

Descriptors: *Maps, *Groundwater, *Water level, *Pumpage, *Drawdown, Water level fluctuations, Irrigation, Water yield, Groundwater availability, Water supply, *Arizona.

Withdrawal of ground water, about 4.0 million acre-feet in Arizona in 1979, is about 200,000 acre-feet less than the amount withdrawn in 1978. The withdrawals in 1978 and 1979 are the smallest since the mid-1950's except in 1966. Nearly all the decrease was in the amount of ground water used for irrigation in the Basin and Range lowlands province. The large amount of water in storage in the surface-water reservoirs, release of water from the reservoirs, floods, and conservation practices contributed to the decrease in ground-water use and caused water-level rises in the Salt River Valley, Gila Bend basin, and Gila River drainage from Painted Rock Dam to Texas Hill. Two small-scale maps show ground-water pumpage by areas and the status of the ground-water inventory in the State. The main map, which is at a scale of 1:500,000, shows potential well production, depth to water in selected wells in spring 1980, and change in water level in selected wells from 1975 to 1980. A brief text summarizes the current ground-water conditions in the State. (USGS)

4C. Effects On Water Of Man's Non-Water Activities

SEASONAL STREAM TEMPERATURE CHANGES FOLLOWING FOREST HARVESTING,
Pennsylvania State Univ., University Park. School of Forest Resources.
G. B. Rishel, J. A. Lynch, and E. S. Corbett.
Journal of Environmental Quality, Vol 11, No 1, p 112-116, January-March, 1982. 2 Fig, 5 Tab, 12 Ref.

Descriptors: *Forest management, *Water temperature, Streams, *Clear-cutting, Cutting management, Forest watersheds, Herbicides, *Seasonal variations, Diurnal distribution.

Changes in water temperature of small, headwater streams were documented following a clearcut-herbicide treatment and a commercial clearcut harvest. The study site was the Leading Ridge Watershed Research Unit about 24 km southwest of State Collete, Pennsylvania. The unit is comprised of three adjacent watersheds that are representative of about 4.0 million ha of Pennsylvania forest. The clearcut herbicide treatment exposed the entire stream channel to direct solar radiation. The average maximum monthly stream temperature increase was 4.4 degrees C. Stream temperatures above 21 degrees C occurred nearly every day during the summer. Temperatures above 25 C were recorded as early as May. Highest stream temperature recorded was 32 degrees C, while on a control watershed stream water temperatures rarely exceeded 20 degrees C. Minimum stream temperatures were as much as 3.9 degrees C lower during the fall and winter months. Diurnal fluctuations also increased, being as high as 17 degrees C, compared to only 4 degrees C on non-treated watersheds. On an adjacent commercially clearcut watershed a buffer zone was left along the perennial stream channels, and only slight changes in stream temperature were noted. (Baker-FRC)

FAMILY LIFE CYCLE DISRUPTION IN RURAL COMMUNITIES: THE CASE OF THE LAKE SHELBYVILLE RESERVOIR,
Illinois Univ. at Urbana-Champaign. Inst. for Environmental Studies.
R. E. Roper, and R. J. Burdge.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-224551, Price codes: A06 in paper copy, A01 in microfiche. Research Report No 166, 102 p, 6 Fig, 4 Tab, 288 Ref. OWRT B-131-ILL(1). 14-34-0001-0218.

Descriptors: *Social impact, *Assessments, *Land acquisition, *Commercial farming, Ethnography, Personal and family life-cycles, Developmental cycles, Career contingencies, *Reservoirs, Construction, Anthropology, *Illinois, Lake Shelbyville, *Rural areas.

This project, assessed on an ex post facto basis, selected impacts upon families and individuals due to the land acquisition program associated with the construction of the Shelbyville Reservoir in east-central Illinois begun in 1962. Research focused on Okaw Township, which borders Lake Shelbyville to the west in Shelby County. The in-depth, individual and family case studies indicated that farm family businesses are not the products of a single generation, or a single family. They are intimately tied to the intergenerational land transfer process which occurs among interconnected families living in close proximity. Thus, the time perspective in examining changes brought about by land acquisition and relocation must be extended on the generational level if the full range of impacts on the local cultural ecology is to be represented. Areawide changes in the impacts on the local cultural ecology is to be represented. Areawide changes in the availability and price of land made the difficult task of reestablishing a family farm even harder for selected families. The Corps' land acquisition policies in 1962 did not consider the generations involved in the establishment of family farms. Furthermore, local residents were critical of the Corps' policies and personnel during the land acquisition process. That historical complaint summarized by the quote, 'the Corps is not a good

LIBRARY U. OF I.. URBANA-CHAMPAIGN

neighbor,' has even today hindered the Corps' ability to manage its relations with area residents and local government units. An understanding of the personal and family life-cycle perspectives on local cultural ecology, coupled with an appreciation of the degree to which rural social processes are bound in time, can strengthen State of Illinois comprehensive planning, decision-making, and review procedures for water and related resource development.

SAWMILL BROOK: AN EXAMPLE OF RAPID GEOMORPHIC CHANGE RELATED TO URBANIZATION,
Wesleyan Univ., Middletown, CT. Dept. of Earth and Environmental Sciences.
C. L. Arnold, P. J. Boison, and P. C. Patton.
Journal of Geology, Vol 90, No 2, p 155-166, March, 1982. 11 Fig, 1 Tab, 24 Ref.

Descriptors: *Urbanization, *Geomorphology, Brooks, Channels, Watersheds, Runoff, Erosion, *Sediment transport, Sedimentation, *Environmental effects, Sawmill Brook, *Connecticut.

The effects that urbanization can have on stream pattern morphology are documented. Such observations can lead to a deeper understanding of the complex-response that can occur in the sediment transport regime as basin-wide sediment yields decline and stream runoff increases. The study area was Sawmill Brook, a tributary of the Mattabesset River, which drains a small watershed in central Connecticut on the northwest fringe of Middletown. Changes in land use were documented by comparison of sequential topographic maps and aerial photographs and from direct field observations. The southern headwater region of the basin has remained forested for the past 45 years. Within the study area reapportionment of agricultural and urban land use took place during 1934 to 1975. Urban development has included a large industrial park, several residential subdivisions, and the construction of an interstate highway through the basin. Associated with this development has been the major alteration of the drainage system in the lower portion of the basin. Runoff from the interstate highway and a portion of the industrial park has been funneled into Fall Brook, which has also been channelized to its confluence with Sawmill Brook. An increased frequency of flooding may be considered the result of short term climatic fluctuations, producing a change in precipitation. The increased frequency of moderate floods, the channel widening, and the change in the sediment transport regime is causing a change from a meandering to a braided channel pattern. With continued urbanization of the basin the present disequilibrium of the channel will be enhanced, resulting in an unstable channel pattern for Sawmill Brook. (Baker-FRC)

RUN-OFF AND INFILTRATION LOSSES RELATED TO SHIFTING AGRICULTURE (JHUM) IN NORTHEASTERN INDIA,
Northeastern Hill Univ., Shillong (India). Dept. of Botany.
O. P. Toky, and P. S. Ramakrishnan.
Environmental Conservation, Vol 8, No 4, p 313-321, Winter, 1981. 10 Fig, 6 Tab, 21 Ref.

Descriptors: *Agricultural hydrology, *Runoff, *Nutrients, Infiltration, India, Percolation, Clearcutting, Vegetation effects, Minerals, Hydrologic cycles, Geochemistry, Fallowing, Monsoons, Jhum agriculture.

In northeast India shifting cultivation (Jhum) involves clearcutting the forest, during the dried biomass, and mixed cropping for 1 or 2 years, followed by a fallow period. In recent times the desirable 20-30 year cycle has been shortened to 4-5 years. Similar freshly-burned fields under 30, 10, and 5 year Jhum cycles and forested fallows of 5 and 10 years regrowth were studied. Nutrients were lost through ash and runoff in all cycles. More ash was liberated and more ash blew away in the 30-year cycle field than in the 5-year cycle field. Calcium losses were high in the 30-year cycle field (broad-leaved trees) and potassium losses were high in the 10-year cycle field (bamboo). Burning also released nutrients (C, N, and S) through volatilization. Runoffs (in cm) during the monsoon period (total 142 cm precipitation) in 1978 were: 5-year, 26.6; 10-year, 33.9; 30-year, 29.4; 5-year fallow, 26.9; and 10-year fallow, 18.5. Sediment losses were 22.5-30.0 tons per ha per year, increasing with shortening of the Jhum cycles, and about 1 ton per ha per year in the 5 and 10-year fallow fields. Percolated water losses were 14-18 cm for the 10 and 30-year Jhum cycles and the 10-yea fallow, and 21-23 cm for the 5-year fallow and 5-year Jhum cycle. Nutrient losses were 5-60 time higher, depending on the mineral, under the three Jhum cycle regimes than in the 10-year fallow. Shortening the Jhum cycle to 4-5 years has adversely affected the vegetation cover and the biological, geochemical, and hydrologic cycles. (Cassar-FRC)

PRELIMINARY MODEL OF AN URBAN FLOODPLAIN UNDER CHANGING LAND USE,
Rice Univ., Houston, TX. Dept. of Environmental Science and Engineering.
D. P. Smith, and P. B. Bedient.
Journal of Hydrology, Vol 51, No 1-4, p 179-185, May, 1981. 2 Fig, 2 Tab, 6 Ref.

Descriptors: *Flood plains, *Urban areas, *Land use, Mathematical models, *Urban watersheds, Urbanization, Flood hydrographs, Detention reservoirs, Design criteria, Flood control, Storm runoff, Brays Bayou, Houston, *Texas.

The hydrologic response of Brays Bayou, a rapidly developing watershed in southwest Houston, was simulated by a computer model using the U.S. Corps of Engineers HEC-1 flood hydrograph package. Existing drainage specification and topographic maps were used to delineate six subwatersheds, while aerial photography was used to reveal current land-use patterns. The modeling effort was designed to predict the effect of urbanization on the runoff pattern of the basin and to test various storm water management alternatives. Unit responses of the six individual subcatchments were generated as functions of various basin parameters and of the extent of urbanization. Several historical storm events at four separate gauges within the Brays watershed were used to calibrate the hydrologic model. The detention storage capacities in the less developed subwatersheds were simulated by placing a reservoir at the outlet of each subwatershed. Detention storage was defined as the additional storage necessary to reduce the peak discharge downstream to a level below the capacity of the channel. A variety of rainfall patterns of different durations and intensities were used to determine the design detention storage for each subwatershed. Land uses were simulated for present conditions and for various development possibilities. Application of the model showed that full-scale development of the Upper Brays Bayou can be expected to overload a flood control system designed to handle the 100-year storm. The current drainage network has been found to be inadequate. Temporary on-site detention of runoff in the upper basin is recommended. (Carroll-FRC)
W82-05642

A REVIEW OF CATCHMENT EXPERIMENTS TO DETERMINE THE EFFECT OF VEGETATION CHANGES ON WATER YIELD AND EVAPOTRANSPIRATION,
Jondershoek Forestry Research Station, Stellenbosch (South Africa).
J. M. Bosch, and J. D. Hewlett.
Journal of Hydrology, Vol 55, No 1/4, p 3-23, 1982. 3 Fig, 2 Tab, 75 Ref.

Descriptors: *Forest hydrology, *Water yield, *Vegetation effects, *Reviews, Land use, *Catchments, *Evapotranspiration, Forest watersheds, Forest management, Clearcutting, Afforestation.

A summary and review of 94 catchment experiments throughout the world revealed several general conclusions on the effects of vegetation changes on water yield. Paired, nested, or grouped catchment experiments produced stronger evidence than less-controlled studies. Results of Hibbert's 1967 review of 39 catchment studies were little changed by the addition of results from 55 more recent investigations. The additional evidence strongly supported his first two generalizations-- (1) reduction of forest cover increases water yield, and (2) establishment of forest cover on sparsely vegetated land decreases water yield. However, the third generalization-response to treatment is highly variable, and for the most part, unpredictable-was not well supported. The present review indicates that vegetation has an influence on water yield as follows: coniferous forest > deciduous hardwood > brush and grass. Changing cover type by 10% produces the following changes in water yield: coniferous and eucalyptus, 40 mm; deciduous hardwoods, 25 mm; and brush and grasslands, 10 mm. Yield changes are greatest in high-rainfall areas, and the effect of clearcutting is shorter-lived than in low-rainfall areas. The annual changes due to treatment in high-rainfall areas are independent of rainfall variation from year to year, but dependent in low-rainfall areas. In low-rainfall areas recovery of water yields is slow because vegetation cover is slow to reestablish. The highest water change in any study was 660 mm per year (relative to bare ground) reported in the Coweeta catchment, North Carolina, where a mixed hardwood forest was 100% clearcut in 1941, regrowth was cut annually, and the area was 100% planted with pine in 1956. (Cassar-FRC)
W82-05647

STORM RUNOFF FROM SMALL LOWLAND CATCHMENTS IN SOUTHWEST ENGLAND,
Imperial College of Science and Technology, London (England).
H. S. Wheater, T. L. Shaw, and J. C. Rutherford.
Journal of Hydrology, Vol 55, No 1/4, p 321-337, 1982. 12 Fig, 2 Tab, 8 Ref.

Descriptors: *Storm runoff, *Urbanization, *Flood peak, Rainfall-runoff relationships, Gloucester, *England, Hydrographs, Soil water, Catchments, Streamflow, Antecedent moisture.

Fifty-five storm runoff events (1970-74) in eight small lowland catchments with clay soils in southwest England were analyzed. Unit hydrograph shape was related to antecedent soil moisture, stream slope, and degree of urbanization. The storm runoff volume was related to soil moisture deficit and to storm rainfall. Dry catchments responded more rapidly to rainfall than wet catchments, with higher peak flow, shorter unit hydrographs, and increased time to peak. The proportion of urbanization was postively correlated with unit hydrograph flow peak and negatively correlated with time-to-peak, with little effect seen for wet catchments and very noticeable effects for dry catchments. Unit hydrograph peak flow increased with channel slope and was negatively correlated with total rainfall volume. Unit hydrograph lag was positively correlated with catchment length and negatively correlated with slope and degree or ubanization. Rainfall loss was independent of

catchment morphology and depended on total rainfall volume and antecedent soil moisture deficit. (Cassar-FRC)
W82-05653

SUBSURFACE FLOW VELOCITIES THROUGH SELECTED FOREST SOILS, SOUTH ISLAND, NEW ZEALAND,
Forest Research Inst. Christchurch (New Zealand).
M. P. Mosley.
Journal of Hydrology, Vol 55, No 1/4, p 65-92, 1982. 7 Fig, 6 Tab, 26 Ref.

Descriptors: *Subsurface flow, *Flow velocity, Forest hydrology, Forest soils, *New Zealand, Tawhai Forest, Big Bush Forest, Craigieburn Forest, Streamflow, Soil water, Antecedent moisture, Hydrology, Soil saturation, Soil porosity, Soil structure, Porosity, Permeability, Bedrock, Root zone, Rainstorms.

Subsurface flow through soils at a total of 51 locations in three New Zealand state forests was investigated by applying water upslope from a pit and determining mean and maximum flow velocities. Mean flow velocity and maximum flow velocity (both in cm per sec), respectively were: Tawhia Forest, undisturbed, 0.1-0.45 and 0.037- 0.67, logged/unburned, 0.020-0.79 and 0.049-2.08, and logged/burned/planted, 0.015-0.64 and 0.072-0.83; Big Bush Forest, 0.-0.93 and 0.055-1.67; and craigieburn Forest, beech forest, 0-0.98 and 0.072-1.67, tussock sites, 0-0.22 and 0.074-0.48. Coefficients of variation were large. There was no significant difference in results from the three different land treatments in Tawhia Forest. Factors affecting subsurface flow were antecedent moisture conditions, soil properties, macropore network, and parent material at the base of the soil. The macropore network was less important in determining hydrological behavior in open-structured soil with a permeable parent material than in less open-structured soil over impermeable bedrock. In Tawhia Forest saturation of the lower soil layers regularly occurs, so that rapid flow through macropores is common and many reach 40% in a small 3-hour storm and 100% in moderate to large rain events. At Big Bush, with less soil moisture and longer slopes, rapid subsurface flow is likely to reach the stream only during larger and longer storms. Craigieburn's drier, deeper soils and permeable underlayer allow less subsurface flow to reach streams during the storm period. (Cassar-FRC)

SLASH BURNING EFFECTS ON SOIL AND WATER CHEMISTRY IN SOUTHEASTERN ALASKA,
Colorado State Univ., Fort Collins. Dept. of Earth Resources.
J. D. Stednick, L. N. Tripp, and R. J. McDonald.
Journal of Soil and Water Conservation, Vol 37, No 2, p 126-128. March/April, 1982. 1 Fig, 3 Tab, 24 Ref.

Descriptors: *Water quality, *Forest fires, *Soil chemistry, *Alaska, Forest management, Forest soils, Nutrients, Water pollution sources, Erosion.

Timber harvest followed by slash burning in the coastal hemlock-spruce forests of Chicagof Island in southeastern Alaska did not produce significant long-term effects on soil or water resources. A 13 ha site, logged in 1977 and burned in June 1978, was monitored by collecting daily stream water samples from above and below the burn during the snow-free months of 1978 and 1979. Soil samples were also analyzed. Suspended sediment levels were higher in the water below the burn (116.8 mg per liter) than above the burn (35.4 mg per liter). Fourteen of the 16 water quality parameters were not significantly different when above-burn and below-burn sample results were compared. However, total P and K levels were higher in below-burn stream water. In soil samples slash burning produced no significant differences in litter depth, pH, N, P, and Ca levels. However, K and Mg concentrations in the burned soil were about half of the control concentrations. (Cassar-FRC)

DRYLAND SALINITY IN A CLOSED DRAINAGE BASIN IN NOBLEFORD, ALBERTA,
Department of Agriculture, Lethbridge (Alberta). Research Station.
T. G. Sommerfeldt, and D. C. MacKay.
Journal of Hydrology, Vol 55, No 1/4, p 25-41, 1982. 7 Fig, 3 Tab, 16

Descriptors: *Drainage, *Closed basins, *Saline soils, Nobleford, *Alberta, Canada, Soil water, Ecological effects, Water management, Land use, Vegetation effects, Fallowing, Range grasses, Cropland.

Factors causing dryland salinity near Nobleford, Alberta, were defined during a 1972-77 study on a site forming a 650 ha dome, which contained a closed basin. Although salinity in the basin was not evident in 1938, two small seeps had appeared by 1954. More than 50 ha of land was salinized by 1973. Studies of well data, precipitation records, rock and soil profiles, snow drifting, and water analysis results indicated that the salinity problems in this basin were a result of disturbances of the natural ecosystem. Native range had been replaced by cereal cropping and summer fallow. Natural drainage patterns had been changed by snow and water retainers and drainage of runoff into the basin. Also contributing to the salinity condition were natural conditions--shallow bedrock in the recharge area, fine soil in the lowland, depressions in bedrock under certain areas, and lack of surface drainage from the basin. Corrective measures are based on discouraging water access in the basin, discontinuing summer fallow, continuous cropping, growing perennial forage crops, removing snow and water retainers, and removing accumulated water from the basin for use in irrigation. EROSION CONTROL POTENTIAL WITH CONSERVATION TILLAGE IN THE LAKE ERIE BASIN: ESTIMATES USING THE UNIVERSAL SOIL LOSS EQUATION AND THE LAND RESOURCE INFORMATION SYSTEM (LRIS),
Ohio State Univ., Columbus. Dept. of Agronomy.
T. J. Logan, D. R. Urban, J. R. Adams, and S. M. Yaksich.
Journal of Soil and Water Conservation, Vol 37, No 1, p 50-55, January/February, 1982. 1 Fig, 8 Tab, 12 Ref.

Descriptors: *Erosion control, *Phosphorus, *Water pollution control, *Lake Erie Basin, *Soil erosion, Cropland, Soil conservation, Cultivation, Soil management, Watershed management, *Cultivation.

Soil loss in the U.S. Lake Erie drainage basin was estimated using the Universal Soil Loss Equation and the U.S. Army Corps of Engineers Land Resources Information System (LRIS). Average annual soil loss was 2.2 tons per acre, with a range of 0.4 to 4.4 tons per acre for individual watersheds. Highest soil losses were in the western and central basins. Basins with the greatest soil losses were the Raisin (Michigan); Maumee, Sandusky, Huron, and Vermilion (Ohio); and Cattaraugus (New York). These watersheds have fine-medium glacial-till derived soils and are highly cultivated, except for the Cattaraugus watershed, which has steep slopes. Reducing soil loss to the tolerance level in all cases would reduce soil loss in the basin as a whole by 40%. The conservation tillage method and the maximum conservation tillage method would reduce soil loss by 46% and 69%, respectively. Methods which made little difference in soil loss were spring plow only and winter cover. Fall plow only actually increased soil loss by 7%. Since a 75% reduction in mean soil loss is necessary to reduce diffuse source phosphorus loads by 50%, none of these methods alone can accomplish this goal. (Cassar-FRC)

WATER YIELD ESTIMATION IN WESTERN UNITED STATES,
Maryland Univ., College Park. Dept. of Civil Engineering.
M. E. Hawley, and R. H. McCuen.
Journal of the Irrigation and Drainage Division, Proceedings of the American Society of Civil Engineers, Vol 108, No IR1, p 25-34, March, 1982. 1 Fig, 6 Tab, 8 Ref.

Descriptors: *Project planning, *Watershed management, *Water yield, Hydrologic models, *Statistical analysis, Mathematical studies, Precipitation(Atmospheric), Vegetation effects, Precipitation intensity, Model studies, Mathematical models, Statistical methods, Prediction, *Western US.

The mean annual water yield of a watershed is used in planning, managing and designing some watershed projects, especially irrigation projects. A statistical study of water yield data from 605 watersheds of noncoastal areas of the western United States was used to develop five equations to estimate the annual water yield of five distinct hydrologic regions. Empirical estimation coupled with regionalization was deemed the most practical method for estimating mean annual water yield. Separation of the study area into five regions significantly improved the accuracy of the estimation. Cluster analysis was used to define the five regions, and a linear mathematical model was developed which explained 57.95% of the variation of the mean annual water yield. The most important predictor of water yield in all regions was the mean annual precipitation, while other variables such as vegetation cover density and precipitation intensity explained smaller amounts of the total variation. EROSIVITY VALUES FOR INDIVIDUAL DESIGN STORMS,
Science and Education Administration, Boise, ID. Northwest Watershed Research Center.
K. R. Cooley.
Journal of the Irrigation and Drainage Division, Proceedings of the American Society of Civil Engineers, Vol 108, No IR1, p 85-87, March, 1982. 1 Tab.

Descriptors: *Mathematical studies, *Error analysis, *Erosion control, *Storm runoff, *Soil conservation, Errors, Erosion, Soil erosion, Storms, Model studies, Mathematical models.

To address the questions raised about the magnitude of errors involved in calculating erosivity values for individual design storms, the value of EI/100 for storm volumes of 2 and 12 inches for durations from 0.5 to 24 hr and for each of four Soil Conservation Service (SCS) storm distributions was determined. The use of various figures in the original paper is explained. Normalizations in

LIBRARY U. OF I., URBANA-CHAMPAIGN

the original work provided better comparisons than did actual storm data of any duration, as compared to the 24-hr SCS distributions suggested by previous investigators. By using long periods of actual storm data, the frequency of storm types likely to occur at a site may be determined. The knowledge of frequency of occurrence of a given storm type may be used in designing soil conservation measures. (Geiger-FRC)

STREAM IMPROVEMENT: THE CHICOD CREEK EPISODE,
Soil Conservation Service, Greenville, NC.
A. Coffey.
Journal of Soil and Water Conservation, Vol 37, No 2, p 80-82, March/April, 1982. 6 Ref.

Descriptors: *Channel improvement, *Watershed management, *Legal aspects, Chicod Creek, North Carolina, Flood control, Sediment control, Environmental effects, Excavation, Monitoring, Fish, Wildlife, Water quality, Water law, Judicial decisions, Flood plain management.

Planned improvements to the clogged and flood prone Chicod Creek, North Carolina, were challenged in a lawsuit November 30, 1971, by a group of five local and national organizations. As a result the project was modified to minimize environmental impacts. Work started in November 1978. Major changes in plans were: wooded swamps were not excavated, only fallen trees and debris were removed; construction was shut down from February 1 to June 30 to avoid interference with herring spawning runs; sediment traps were constructed at critical points; 15 ft wide grass strips were established on banks in non-forested land; channels were excavated from one side only; spoil banks were placed 15 ft from the channel bank in critical areas and were seeded with stabilizing vegetation; clumps of trees were preserved at 200-300 ft intervals; and channel banks were sloped 1:1 except for some experimental areas with 2:1 and 3:1 slopes. Monitoring of fish and wildlife, water quality, and groundwater condition was started before construction and will continue until about 1986. As a result of this landmark suit, watershed planning has become more comprehensive and considerate of environmental values. (Cassar-FRC)

MODELING SEDIMENT YIELDS FROM AGRICULTURAL WATERSHEDS,
Purdue Univ., Lafayette, IN. Dept. of Agricultural Engineering.
D. B. Beasley, L. F. Huggins, and E. J. Monke.
Journal of Soil and Water Conservation, Vol 37, No 2, p 113-117, March/April, 1982. 4 Fig, 1 Tab, 9 Ref.

Descriptors: *Agricultural watersheds, *Watershed management, *Sediment yield, Cultivation, Model studies, ANSWERS model, Indiana, Black Creek, Erosion control, Nonpoint source pollution, Soil conservation.

Distributed parameter models are potentially more accurate than lumped parameter models in estimating sediment yields. A distributed parameter model, ANSWERS (Areal Nonpoint Source Watershed Environment Response Simulation) was applied to a 714-ha agricultural watershed in the Black Creek Basin, Indiana. Rainfall amount and total sediment yield were predicted within 13% of observed amounts. Simulation of sediment yield under different tillage practices showed that chisel plowing produced one-third less sediment than the prevailing practice, fall moldboard plowing. Closer examination of two small high-erosion sections, combined area 32 ha, showed that changing to chisel plowing only in these small sections would account for 40% of the sediment yield reduction that would be achieved if the entire watershed were chisel plowed. USING THE ANSWERS MODEL TO ESTIMATE SEDIMENT YIELDS ON CONSTRUCTION SITES,
Guam Univ., Agana. Water and Energy Research Inst.
T. A. Dillaha, III, D. B. Beasley, and L. F. Huggins.
Journal of Soil and Water Conservation, vol 37, No 2, p 117-120, March/April, 1982. 4 Fig, 1 Tab, 8 Ref.

Descriptors: *Sediment yield, *Construction, *Watershed management, ANSWERS model, Model studies, Erosion control, Runoff, Alternative planning, Land management, Soil conservation.

ANSWERS (Areal Nonpoint source Watershed Environment Rresponse Simulation), a disributed parameter model designed for use in agricultural watersheds, was used to evaluate solutions to runoff and erosion from construction activities. A residential development was being built in a 53-ha watershed with slopes of 0-17% in which 95% of the land had been used for row crops (corn), 15% trees, and 2% swampy lowlands. The design storm, 5.28 cm of rainfall within 1.5 hours, produced from 5,100 (chisel plowing) to 16,300 (fallow) kg per ha of sediment under the 12 tested alternatives. The agricultural conditions before development (corn) yielded 13,500 kg per ha. Construction by scalped topsoil with bare roadways, gravel roadways, or paved roadways yielded 16,000, 14,500, and 15,400 kg per ha, respectively. Scaled, but seeded and mulched areas with bare roadways or gravel roadways produced 12,700 and 9,800 kg per ha sediment, respectively. Land left as crop residues and weeds with bare roadways or gravel roadways reduced sediment losses to 11,500 and 6,900 kg per ha, respectively. The practice of scaled topsoil with bare roadways and sediment basisns or diversion structures allowed 13,800 and 15,500 kg per ha losses, respectively. Model results were consistent with the few available field observations at the construction site. (Cassar-FRC)

5. WATER QUALITY MANAGEMENT AND PROTECTION

5A. Identification Of Pollutants

COMPARISON OF VARIOUS BACTERIAL INDICATORS OF FECAL CONTAMINATION OF THE SEINE IN THE PARIS REGION (COMPARISON DE DIFFERENTS INDICATEURS BACTERIENS DE CONTAMINATION FECALE SUR LA SEINE EN REGION PARISIENNE),
Societe Lyonnaise des Eaux et de l'Eclairage (France).
M. Rizet.
Aqua, No 7, p 150-152, July, 1980. 1 Fig, 2 Tab. (English summary).

Descriptors: *Bacterial analysis, *Water quality, *Indicators, *Seine River, Paris, Feces, Coliforms, *Bioindicators, Variation coefficient, Mathematical studies, Water pollution, *Pollutant identification.

Water samples were collected approximately weekly at four potable water plant intakes in the Paris area and subjected to comparative bacterial counts. Fecal coliforms were counted on Chapman TTC medium, sulfite reducing clostridium (Clostridium perfringens) on Bacto SPS agar medium, and fecal streptococci on Stranetz and Bartley medium, in each case following concentration by membrane filtration. The maximum amplitudes of variation in bacterial counts between the two treatment plants farthest apart, based on the annual means, were 26 for fecal coliforms, 18 for fecal streptococci and 8 for clostridium. Thus the fecal coliform count seems to be the most sensitive of the three indicators investigated. Variations from the mean at a single point were 76% for fecal coliforms, 107% for fecal streptococci and 120% for clostridium. The bacterial as well as physical and chemical analyses of the Seine water demonstrated increasing deterioration of water quality from upstream to downstream of Paris. (Carroll-FRC)

BORON STATUS OF BERLIN WATERS (BORSTATUS BERLINER GEWASSER),
Technische Univ., Berlin (Germany, F.R.). Inst. fuer Okologie.
H. P. Blume, R. Bornkamm, T. Kempf, S. Muljadi, and F. Raghi-Atri.
Archiv fur Hydrobiologie, Vol 89, No 4, p 426-439, August, 1980. 4 Fig, 10 Tab, 17 Ref.

Descriptors: *Boron, *Lakes, *Chemical analysis, *Nutrients, Drinking water, *Berlin, Germany, Water pollution sources, Phosphorus removal, Chemical precipitation, Lime.

Boron is a micronutrient of widespread occurrence, which may be toxic to crops at higher concentrations. Substantial increases in boron contents of some German waterbodies have occurrent in recent years due to increased use of boron-containing fertilizers, pharmaceuticals, laundry bleaches, and other chemicals. The boron levels were investigated in the Tegeler See, Oberhavel, Heiligensee, and Pechsee, four lakes in the Berlin watershed. The Tegeler See receives wastewater effluents and is considered polluted. In 1975-76 the Tegeler See had a mean boron content of 0.2 mg/l; the Nordgraben, its principal feed stream, contained 0.6 mg/l. Boron contents in the Heiligensee and Pechsee were below 0.1 mg/l. Seasonal variations in the Tegeler See were small, while the large variations in the Heiligensee were attributed to occational occurrence of backup from the Havel as well as to biological binding and precipitation. Boron accumulations were also determined in the biocenosis and the sediment of the lakes. The present boron levels and rates of increase (ca. 5%/yr) appear to present no threat to drinking water quality if water is obtained from wells into which lake water infiltrates. Combined use of lime and iron chloride for phosphate removal from lake influents would have the side effect of removing most of the boron and heavy metals. (Carroll-FRC)

MYTILUS CALIFORNIANUS AS A BIOINDICATOR OF TRACE METAL POLLUTION: VARIABILITY AND STATISTICAL CONSIDERATIONS,
Moss Landing Marine Lab., CA.
M. Gordon, G. A. Knauer, and J. H. Martin.
Marine Pollution Bulletin, Vol 11, No 7, p 195-198, July, 1980. 1 Fig, 3 Tab, 15 Ref.

Descriptors: *Bioindicators, *Trace metals, Mytilus, Mussels, Water pollution, Pollutants, Indicators, Aluminum, Cadmium, Lead, Chromium, Iron, Nickel, Copper, Zinc, Aquatic populations, *Pollutant identification.

Mytilus californianus is a commonly used trace metal bioindicator species. This study investigated the natural variability of this mussell by analyzing specimens collected from two sites in the Southern California Bight for their aluminum, cadmium, chromium, copper, iron, nickel, lead, and zinc contents. Factors which can contribute to the observed population variability include water temperature, salinity, and with in-site variation. This variance should be minimized in order to maximize the ability to resolve differences in mean trace metal levels between populations in relation to a given independent variable. When M. californianus is used as the bioindicator, increases or decreases in metal concentrations on the order of 15 to 40 percent must occur if significant differences are to be detected by analyzing 30 individuals from each site. In general, analysis of between 10 and 30 individuals was required to yield maximum resolution in terms of trace metal concentration between population means while maintaining cost effectiveness. The number of samples required to detect a

given difference may vary from year to year or from site to site, necessitating the determination of population variance estimates for each collection site. The technique of pooling many individual organisms into a single sample may be used to increase resolution and reduce analytical load. However, a variability study using individual samples should still be used as the first step in any baseline or monitoring program. (Carroll-FRC)

APPARATUS NEEDS AND COSTS FOR MONITORING PRIORITY POLLUTANTS,
Ohio River Valley Water Sanitation Commission, Cincinnati.
A. H. Vicory, Jr., and J. F. Malina, Jr.
Journal of the Water Pollution Control Federation, Vol 54, No 2, p 125-128, February, 1981. 1 Fig, 5 Ref.

Descriptors: *Laboratory equipment, *Monitoring, *Water analysis, *Pollutant identification, Wastewater analysis, Priority pollutants, Organic compounds, Metals, Pesticides, Chromatoraphy, Costs.

This report, prepared by the Water Pollution Control Federation Toxic Substances Committee, described the equipment and resources needed for monitoring toxic materials in wastewater effluent and natural waters. Analysis of the 127 compounds on the priority pollutant list requires a gas chromatograph-mass spectrometer for organic and miscellaneous compounds (minimum $75,000), a purge and trap attachment for the chromatograph ($5500) for purgeable organics, equipment for base/neutral extractables ($2500), flame ionization detector or electron capture devices for the chromatograph to isolate acid-extractable organics ($4000), pesticide analysis equipment ($2500), and atomic absorption spectrophotometer and associated equipment (up to $20,000) and colorimetric apparatus (up to $6000) for metals and cyanides. A recently built 2600 sq ft facility for wastewater effluent analysis cost $250,000, excluding costs of land, utilities, and instruments. Operating costs including salaries for an analytical facility are a minimum of $100,000 per year. Analytical costs per sample range from $10 to $2000. Monitoring priority pollutants in natural waters requires a minimum investment of $30,000 for equipment and $10,000 annual operating costs based on 1 sample per day, 5 days per week. (Cassar-FRC)

RELIABILITY OF ANALYTICAL METHODS FOR ANAEROBIC MUNICIPAL SOLID WASTE SAMPLES,
Miami Univ., FL. Dept. of Mechanical Engineering.
E. L. Daly, Jr., and S. Farooq.
Journal of the Water Pollution Control Federation, Vol 54, No 2, p 187-192, February, 1982. 5 Fig, 4 Tab, 5 Ref.

Descriptors: *Chemical analysis, *Precision, *Solid wastes, *Pollutant identification, Heavy metals, Metals, Nitrogen compounds, Ammonia, Nitrates, Nitrites, Phosphorus, Chloride, Chemical oxygen demand, Sulfides, Anaerobic digestion, Municipal wastes.

Samples of anaerobically digested municipal refuse were spiked with 1 to 2.5 times the normal level of the constituent of interest to test the reliability of standard analtyical methods as described in 'Standard Methods' and EPA's Level One Assessment. Samples were spiked with a single chemical or a mixture of substances. Statistical analysis of the data showed that relative recoveries of singly-spiked substances were: total organic nitrogen, 93%; ammonia N, 84.1%; nitrite N, 119%; nitrate N, 44%; total phosphorus, 157%; chloride, 104%; COD, 70%; total organic carbon, 65%; sulfide, 80%; zinc, 86.1% calcium, 174%; iron, 86%; manganese, 75.1%; nickel, 88.5%; cobalt, 154%, cadmium, 56.7%; copper, 111%; and chromium, 101%. Recoveries for nearly two thirds of the 18 parameters were within the range 80-120%. Analytical precision was about 10% for most of the parameters analyzed. In the composite spike samples self-interferences produced recoveries from -0.11% to 502% in a distilled water matrix and -33.3% to 805% in an effluent filtrate matrix. These results emphasize the importance of conducting spiking experiments individually or with an appropriate control. (Cassar-FRC)

GAS-CHROMATOGRAPHIC SPECIATION OF METHYLSTANNANES IN THE CHESAPEAKE BAY USING PURGE TRAP SAMPLING WITH A TIN-SELECTIVE DECTOR,
National Bureau of Standards, Washington, DC.
J. A. A. Jackson, W. R. Blair, F. E. Brinckman, and W. P. Iverson.
Environmental Science and Technology, Vol 16, No 2, p 110-119, February, 1982. 8 Ffig, 3 Tab, 31 Ref.

Descriptors: *Chemical analysis, *Bays, Chromatography, Organotin compounds, Metabolism, Organometallic compounds, Photometry, Flame photometry, Tin, Heavy metals, *Chesapeake Bay, *Pollution identification.

A method is presented which permits detection and speciation of both volatile and nonvolatile organotin compounds in aqueous media. The method makes use of a commercial gas chromatograph with a flame photometric detector optimized for tin-selective detection. The purge volatiles and species volatilized by hydridization with NaBH4 were concentrated by a commercial automatic purge and trap sampler employing a Ttenax-GC filled trap. Varying amounts of methyltin compounds were detected by the method, including tetramethyltin and methyltin hydrides, in polluted sites in Baltimore Harbor. Gas chromatography-mass spectrometry was used to confirm earlier reports of microbial methylation of inorganic tin by a strain of Pseudomonas isolated from the Chesapeake Bay. Biogenic origins are thus suspected for the methylstannanes found in the Bay area. (Baker-FRC)

ANODIC STRIPPING VOLTAMMETRY AS AN ANALYTICAL TOOL,
New Mexico State Univ., Las Cruces. Dept. of Chemistry.
J. Wang.
Environmental Science and Technology, Vol 16, No 2, p 104A-109A, 1982. 2 Fig, 1 Tab, 50 Ref.

Descriptors: *Heavy metals, *Water analysis, Measuring instruments, *Anodic stripping voltammetry, Pollution load, Monitoring, Water quality, Water pollution control.

Anodic stripping voltammetry has been used extensively to analyze natural water samples. Beginning in the 1970s ASV has been widely used for analyzing about 20 trace metals in different types of natural waters such as oceans, lakes, rivers, and sewage and industrial effluents, along with tap water. The more sensitive version of ASV, involving the sensitive differential pulse excitation ramp during the stripping step, is usually employed for measuring ultratrace concentration levels of some toxic metals such as thallium, lead, and cadmium in seawater and inland waters. The advantages of using ASV for measuring trace metals in natural water are the direct analysis capability, elimination of concentration steps, and minimum use of reagents. ASV is subject to many potential interferences due to the myriad of variances, such as surfactants, metals, and ligands present in natural waters. An important feature of ASV is its capability to differentiate various chemical forms of a given trace metal in solution, in contrast to atomic absorption or neutron activation, which measure the total metal content. ANALYSIS OF VOLATILE ORGANIC COMPOUNDS IN WATER, WASTE WATER AND AN INDUSTRIAL EFFLUENT,
Imperial Coll. of Science and Technology. London (England). Public Health Engineering Lab.
P. Leinster, A. E. McIntyre, J. N. Lester, and R. Perry.
Chemosphere, Vol 10, No 3, p 291-301, March, 1981. 9 Fig, 1 Tab, 13 Ref.

Descriptors: *Organic compounds, *Volatile compounds, *Industrial wastewater, Chlorinated hydrocarbons, Chloroalkanes, *Pollutant identification, Water analysis, Wastewater analysis, Extraction, Solvent extraction, Gas purging, Adsorption.

Three methods for removing volatile organic compounds from water samples prior to gas-liquid chromatographic analysis were evaluated. These methods were solvent extraction, gas sparging, and closed-loop stripping. Water samples spiked with a mixture of n-chloroalkanes (C8-C18) were used as standards. Using dichloromethane as an extraction solvent, chloroalkane recoveries were 42-66%, increasing with increasing alkly chain length. Hexane, cyclohexane, and diethyl ether recovered 20-45% of the chloroalkanes. In the gas sparging technique, recovery of organics increased with increasing helium volumes from 2 to 12 liters. Recovery decreased with increasing chloroalkane chain length from 65%-100% at C8 to < 20% at C18. A 55 C sparging temperature gave better recovery than 30 C and 21 C from C8 to C14. Recovery at all three temperatures decreased to about 10% at C18. Closed-loop stripping for 40 hours completely recovered C8 to C12 chloroalkanes but only 10-70% of the higher alkanes. Recoveries of all compounds increased with temperature, especially the higher molecular weight materials. Analysis of a trade effluent containing high levels of volatile organic compounds, sewage, sewage effluents, river water, and air samples after using each of the three extraction methods produced very different results. Each method removed a different porportion of the constituents. Solvent extraction with dichloromethane removed the widest range of compounds. It is likely that more than one extraction method must be used to obtain extensive information about the organic constituents of a water sample. (Cassar-FRC)

GAS CHROMATOGRAPHIC DETERMINATION OF PHENOLIC COMPOUNDS IN WATER, AS THEIR PENTAFLUOROBENZOYL DERIVATIVES,
Stockholm Univ. (Sweden).
L. Renberg.
Chemosphere, Vol 110, No 7, p 767-773, July, 1981. 2 Fig, 1 Tab, 23 Ref.

Descriptors: *Phenols, *Wastewater analysis, *Pollutant identification, *Gas chromatography, Water analysis, Organic compounds, Fluorobenzoylation.

Phenolic compounds in water and wastewater were determined by gas chromatography-mass spectrometry after conversion to the pentafluorobenzoyl derivatives and extraction into an organic solvent. No isolation step was necessary before the derivatization procedure. Test substances were phenol, 2,4-dimethylphenol, 4-chloro-2-cresol, 4-hloroe-e-cresol, 2-chlorophenol, 2,4-dichlorophenol, and 2-hydroxy-5-chlorodiphenylmethane. Precision of the method was 3.1-6.6% relative standard deviation. The method was linear within the 0.001 to 10 mg per liter range. Comparisons with the pentafluorobenzylation method showed that the pentafluorobenzoylation method was faster and had less background on the chromatogram. (Cassar-FRC)

Descriptors: *Bioindicators, *Heavy metals, *Algae, *Indicators, Metals, Trace metals, Water analysis, Chara corallina, Accumulation, Bioaccumulation, X-ray emission analysis, Aquatic plants, Pollutant identification, *Fate of pollutants.

Trace metals in water were determined by charged particle induced X-ray emission (PIXE) analysis of Chara corallina, a fresh water alga with large (1 cm x 1 mm), easily-located internodal cells. This alga accumulates metals in its cell walls. After 1 day incubation in water supplemented with 0.01 mM heavy metal ions, the algal cell walls concentrated metals by a factor as large as 1000. Cu, Zn, and Hg were preferentially accumulated. Other metals used in the study were Fe, Sr, Ba, Pb, Ag, and Cd. cu accumulation rates were greater in 0.1 mM solutions than in the lower concentrations tested. This alga is a useful indicator plant for heavy metals. (Cassar-FRC)

RECENT TRENDS OF BIOCIDES IN PIKES OF THE LAKE PAIJANNE,
Jyvaeskylae Univ. (Finland). Dept. of Chemistry.
J. Paasivirta, J. Sarkka, M. Aho, K. Surma-Aho, and J. Tarhanen.
Chemosphere, Vol 10, No 4, p 405-414, April, 1981. 5 Fig, 1 Tab, 13 Ref.

Descriptors: *Fish, *Mercury, *Chlorinated hydrocarbons, *Lake Paijanne, *Finland, *Pike, Methylmecury, Organic compounds, Insecticides, Pulp and paper industry, Phenols, Fate of pollutants, Pollutant identification.

Pike (Esox lucius) were sampled in May 1980 in three areas of Lake Paijanne, Finland, and analyzed for several pollutants. Average mercury levels were as follows: total Hg, 642 + or - 204 ng per g; and methylmercury, 83.21 + or - 11.11%. Other contaminants monitored were HCB, DDE, polychlorinated biphenyls, 2,4,6-trichlorophenol, 2,3,4,6-tetrachlorophenol, tetrachloroguaiacol, pentachlorophenol, and tetrachlorocatechol. Levels of these chemicals were variable. Although pentachlorophenol concentrations were 10-70 ppb (fresh weight) in all three locations of the lake, the other chemicals associated with pulp and paper manufacture were found in abundance only at Tiirinselka. Regression analysis of the current findings and previous results showed a decreasing trend in Hg levels in fish tissue from 1970 to the present. Curves were developed to predict Hg levels to 1984, based on the fact that Hg pollution of the lake stopped in 1968. (Cassar-FRC)
W82-04819

OCCURRENCE AND DETERMINATION OF ORGANIC OXIDANTS IN RIVERS AND WASTEWATERS,
Illinois Univ at Urbana-Champaign. Inst. for Environmental Studies.
R. A. Larson, K. Smykowski, and L. L. Hunt.
Chemosphere, Vol 10, No 11/12, p 1335-1338, November/December 1981. 1 Tab, 12 Ref.

Descriptors: *Organic compounds, *Oxidation, *Pollutant identification, *Wastewater analysis, *Raw water, Water analysis, Rivers, Iodometric methods, Disinfection, Chemical analysis.

A spectrophotometric iodometric method, using two concentration procedures, was used to detect organic oxidants in river water and wastewater. Examples of oxidants under consideration are chloramines, quinones, and hydroxyhydroperoxides. Recovery of two known peroxides indicated that the concentration method using ion exchange was 80-85% efficient, and dichloromethane extraction, 70-82% efficient. Organic oxidants were detected in water samples as follows: Henry, Illinois, municipal wastewater, 2.5 times 10 to the minus 5th power M; Delaware River, Chester, Pennsylvania, 8.6 times 10 to the minus 6th power M; Brandywine Creek Wilmington, Delaware, 5.8 times 10 to the minus 6th power M; Delaware River, New Castle, Delaware, 2.7 times 10 to the minus 6th power M; Christiana River at Wilmington, 1.6 times 10 to the minus 7th power M; Boneyard Creek, Urbana, Illinois, 1.4 times 10 to the minus 7th power M; and Crystal Lake, Urbana, Illinois, 1.3 times 10 to the minus 7th power. Other samples of municipal water, Wastewater, and river water gave values in the range of 10 to the minus 8th power, the lowest detectable limit. (Cassar-FRC)

UNUSUAL POLYHALOGENATED CHEMICAL RESIDUES IDENTIFIED IN FISH TISSUE FROM THE ENVIRONMENT,
Environmental Research Lab.-Duluth, MN.
D. W. Kuehl.
Chemosphere, Vol 10, No 3, p 231-242, March, 1981. 86 Ref.

Descriptors: *Chlorinated hydrocarbons, *Fish, *Pesticides, *Pollutant identification, Bioassay, Organic compounds, Chemical wastes, Brominated compounds, Water pollution sources, Reviews.

Unusual polyhalogenated compounds identified in fish are the subject of a review of the 1970-80 literature. Not included are papers on routine monitoring or papers describing laboratory bioassays. Some of the compounds were pesticides, their metabolites, or their manufacturing intermediates: methylthiopentachlorobenzene and di-(methylthio)tetrachlorobenzene, dimethyltetrachloroterephthalate, chloronorbornadiene and chloronorborene compounds, polychlorinated dibenzo-p-dioxins, trifluralin, 1,3,5-trichloro-2-(4-nitrophenoxy)benzene, polychloro-2-(chloromethylsulfonamide) diphenyl ethers and metabolic products, pentachlorophenol, dichlorobenzophenone, hexachlorobenzene, mirex, kepone, chlordene epoxide, 1-hydrolychlordene, and toxaphene. Industrial chemicals and their intermediates are chlorofluorotoluene mixture, hexachloro-1,3-butadiene, 2,4,6-trichlorophenol, isomers of chloroguaiacol, polychlorinated dibenzofurans, polychlorinated terpehnyls, polychlorinated styrene, and 2-chloroaniline, Many brominated compounds were found in fish living in waters receiving effluents disinfected with bromine chloride. Other compounds include chloramines, trichlorophenol, pentachloroanisole, and polychlorinated napthalenes. (Cassar-FRC)

ANALYSIS OF MARINE SEDIMENT, WATER AND BIOTA FOR SELECTED ORGANIC POLLUTANTS,
Texas A and M Univ., College Station. Dept. of Chemistry.
H. E. Murray, L. E. Ray, and C. S. Giam.
Chemosphere, Vol 10, No 11/12, p 1327-1334, November/December, 1981. 1 Fig, 2 Tab, 30 Ref.

Descriptors: *Sediments, *Marine animals, *Aromatic compounds, *Pollutant identification, Organic compounds, Pesticides, Benzo(a)pyrene, Hexzachlorobenzene, Pentachlorophenol, Chlorinated hydrocarbons, Phenols, *San Luis Pass, *Texas, Marine sediments, Water analysis, Polycyclic aromatic hydrocarbons, Fish, Phthalates, Crabs, Squid, Shrimp.

Water, sediments, and biota collected from San Luis Pass, West Galveston Bay, Texas, in February-June 1980 were analyzed for organic pollutants. Water samples had no detectable hexachlorobenzene (HCB) or benzo(a)pyrene (BaP); pentachlorophenol (PCP) concentrations were 4.3-11 ng per liter. Average pollutantconcentrations in sediments were (ng per g dry weight); HCB, 0.49; BaP, 2.2; PCP, 0.18; dibutyl phthalate, 60; di(2-ethylhexyl) phthalate, 94; diethyl phthalate, 5; and polychlorinated biphenyls, 0.52, DDE, DDT, chlordane and dieldrin were all below the detection limits of 0103 ng per g. BaP levels in biota were all below the detection limit of 0101 ng per g wet weight. Average HCB concentrations in biota (ng per g wet weight) were: flounder, 049; longnose killifish, 0.65; brown shrimp, 0.88; blue crab, 9.6; and dwarf squid, 0.71. Average PCP levels in biota were (ng per g wet weight): flounder, 2.6; longnose killifish, 5.3; brown shrimp, 7.5; blue crab, 2.8; and dwarf squid, 1.9. The order of concentrations in biota (except blue crab) was PCP > HCB > BaP; in sedimentsat the site where the biota were collected, BaP > NCB > PCP. This indicates that the concentrations of pollutants in sediments may not accurately indicate the exposure of animals which do not ingest large quantities of sediments. (Cassar-FRC)

CONTENTS OF CHLORDANE-, PCB- AND DDT-COMPOUNDS AND THE BIOTRANSFORMATION CAPACITY OF FISHES IN THE LAKE AREA OF EASTERN FINLAND,
Finland Technical Research Center, Espoo.
H. Pyysalo, K. Wickstrom, R. Litmanen, P. Lindstrom-Seppa, and U. Koivusarri.
Chemosphere, Vol 10, No 8, p 865-876, August, 1981. 3 Fig, 2 Tab, 26 Ref.

Descriptors: *Fish, *Biotransformation, *Insecticides, Perch, Roach, Vendace, Trout, *Finland, Chlordane, DDT, Polychlorinated biphenyls, *Lakes, Organic compounds, Chlorinated hydrocarbons, Pesticides, *Pollutant identification, Fate of pollutants.

Chlordane compounds were detected in fish (perch, roach, vendace, and rainbow trout) in lakes of eastern Finland. Since chlordane has not been used in this region, there is a possibility that it was transported by air. Concentrations of three chlordane isomers, DDT, and polychlorinated biphenyls were reported for muscles and liver of the fish. Pollutant levels appeared to be negatively correlated with the biotransformation capacity of the fish species. Highest concentrations of pollutants were found in vendace, which had the poorest monooxygenase and conjugating activity. Rainbow trout, with the greatest biotransformation ability of the group, had the lowest pesticide levels. Perch and roach were intermediate in pesticides levels and biotransformation capacity. (Cassar-FRC)

ORGANOCHLORINE POLLUTANT ANALYSIS OF CONTAMINATED AND UNCONTAMINATED LAKE SEDIMENTS BY HIGH RESOLUTION GAS CHROMATOGRAPHY,
Ulm Univ. (Germany, F. R.).
H. Buchert, S. Bihler, P. Schott, H. P. Roper, and H. J. Pachur.
Chemosphere, Vol 10, No 8, p 945-956, August, 1981. 5 Fig, 3 Tab, 16 Ref.

Descriptors: *Chlorinated hydrocarbons, *Lake sediments, *Pesticides, Lakes, Sediments, *Organochlorine, *Pollutant identification, Accumulation, Polychlorinated biphenyls, Polychlorinated terphenyls, DDT, DDE, DDD, Organic compounds, Gas chromatography, Hexachlorocyclohexane.

Samples of sediments from several German lakes in industrial areas contained a variety of organochlorine pollutants, including chlorobenzenes (tri-, tetra-, penta-, and hexa-), isomers of HCH, isomers of DDT, polychlorinated biphenyls, and polychlorinated terphenyls. Maximum concentrations of several pollutants were (in micrograms per kg dry weight): HCB, 15; alpha-hexachlorocyclohexane (HCH), 316; gamma HCH, 156; 4,4'-DDE, 499; 4,4'-DDD, 747; 4,4'-DDT, 188; polychlorinated biphenyls (PCB) (60% C1), 1200; and polychlorinated terphenyls (PCT) (54% C1), 1200. Even at a depth of 6 m, traces of organochlorine compounds were detected in one lake. Surface sediments of a salt lake in Libya had traces of HCB, PCB, 4,4'-DDE, 4,4'-DDD, and 4,4'-DDT. Sediments from a rural German lake showed traces of PCB, 4,4'-DDE, and 4,4'-DDD at depth levels corresponding to the year 1920. (Cassar-FRC)

PERSISTENT ORGANIC CHEMICALS IN SEWAGE EFFLUENTS: I. IDENTIFICATIONS OF NONYLPHENOLS AND NONYLPHENOLETHOXYLATES BY GLASS CAPILLARY GAS CHROMATOGRAPHY/MASS SPECTROMETRY,
Eidgenoessische Anstalt fuer Wasserversorgung, Abwasserreinigung und Gewaesserschutz, Zurich (Switzerland).
W. Giger, E. Stephanou, and C. Schaffner.

Chemosphere, Vol 10, No 11/12, p 1253-1263, November/December, 1981. 3 Fig, 1 Tab, 18 Ref.

Descriptors: *Phenols, *Surfactants, *Pollutant identification, Organic compounds, Nonylphenols, Effluents, Rivers, *Zurich, Switzerland, *Glatt River, Gas chromatography, Mass spectrometry.

Nonylphenols and nonylphenolethoxylates containing 1 to 3 oxyethylene groups were detected in effluents from activated sludge sewage treatment plants in Zurich, Switzerland. Concentrations were estimated at 100-300 micrograms per liter. In addition, several samples contained an octylphenoldiethoxylate. These compounds are persistent metabolites of nonionic detergents. Chromatograms and mass spectra of these compounds are presented. Water samples from the River Glatt, flowing through a densely populated area east of Zurich, contained nonylphenol and mono- and diethoxylated nonylphenol. (Cassar-FRC)

AUTOMATIC MONITORING OF COPPER IN WASTE WATER FROM PLATING SHOPS,
Siemens Naamloze Vennootschap, Oostkamp (Belgium).
J. B. Vanhumbeeck.
Water Science and Technology, Vol 13, No 11-12, p 539-544, 1981. 1 Fig.

Descriptors: *Copper, *Monitoring, *Computers, *Process control, *Colorimetry, Electroplating, Wastewater treatment, *Industrial wastes, Heavy metals, Automation, Control systems, Water analysis, Pollutant identification, Water quality control.

Wastewater from plating shops can be monitored for copper before entering the treatment regime, during the process for operation control or when leaving the plant site for emission control. A continuous monitoring process for copper levels in the discharge waters is usually required due to unreliable removal processes for this toxic heavy metal. An automatic monitoring system was developed based on the German standard colorimetric method using bathocuproin sulphonic acid. The analytical procedure was optimized, and the mechanical system was made simple, durable and easy to maintain. A simple microcomputer and data treatment system was added to control the automated monitoring process, rendering a reliable but practical copper control program for use under normal process conditions. HIGH-PERFORMANCE LIQUID CHROMATOGRAPHIC DETERMINATION OF NITRITE IN ENVIRONMENTAL SAMPLES BY THE USE OF HYDRALAZINE,
University of Occupational and Environmental Health, Kitakyushu (Japan). School of Medicine.
H. Noda, M. Minemoto, and T. Asahara.
Journal of Chromatography, Vol 235, No 1, p 187-195, 1982. 8 Fig, 1 Tab, 19 Ref.

Descriptors: *Nitrites, *Water analysis, Chemical analysis, Environmental protection, *Chromatography, Pollutant identification.

The usefulness of the high-pressure liquid chromatographic method is described for the determination of nitrite ion in environmental samples, particularly in biological fluids, foods and ambient waters. The procedure makes use of UV and fluorometric detectors. Hydralazine reacts with nitrite ion under acidic conditions at 37 degrees C to form tetrazolo (5,1-alpha)phthalazine (Tetra-P) almost quantitatively. The determination of Tetra-P by reversed-phase high-pressure liquid chromatography was simple, specific, sensitive and reliable over the range of 0.001-0.10 ppm of nitrite nitrogen. The hydralazine procedure is one of the most useful methods for routine analysis of nitrites in environmental samples. (Baker-FRC)

POLYCYCLIC AROMATIC HYDROCARBONS IN SEDIMENTS AND ASSOCIATED BENTHOS IN LAKE ERIE,
National Oceanic and Atmospheric Administration, Ann Arbor, MI. Great Lakes Environmental Research Lab.
B. J. Eadie, W. Faust, W. S. Gardner, and T. Nalepa.
Chemosphere, Vol 11, No 2, p 185-191, 1982. 3 Fig, 1 Tab, 16 Ref.

Descriptors: *Lake sediments, *Aromatic compounds, *Benthic fauna, *Polyaromatic hydrocarbons, *Lake Erie, Sediments, Powerplants, Worms, Midges, Invertebrates, Aquatic fauna, Water pollution sources, Fate of pollutants, Water pollution effects.

Polyaromatic hydrocarbons (PAH) in lake surface sediments near a large coal fired powerplant on the Michigan shore of Lake Erie ranged from 0.54 to 3.75 ppm total PAH. Stations south of the plant had much lower concentrations than stations north of the plant. There was a significant correlation between percent organic matter and PAH content of the sediment. Worms and midges were scarce at the northern stations because PAH concentrations were near or above the 96 hour LC50. Oligochaete worms did not bioaccumulate PAH, but some biodegradation was noted. Midges within 1 km of the shore had the highest PAH levels. These decreased with increasing distance offshore. Midges bioaccumulated phenanthrene, fluoranthene, pyrene, chrysene, and benzo(a)pyrene. The River Raisin appeared to be a source of PAH. No point source at the powerplant was evident. Combustion products were well dispersed, and coal leachate was small in quantity. Concentrations of PAH were similar to those measured in other industrial areas. (Cassar-FRC)

DETERMINATION OF 2,3,7,8-TETRACHLORODIBENZO-P-DIOXIN IN FRESH WATER FISH,
Health Effects Research Lab., Research Triangle Park, NC.
R. L. Harless, E. O. Oswald, R. G. Lewis, A. E. Dupuy, Jr., and D. D. McDaniel.
Chemosphere, Vol 11, No 2, p 193-198, 1982. 2 Fig, 2 Tab, 21 Ref.

Descriptors: *Fish, *Chlorinated compounds, *Dioxins, Organic compounds, *Pollutant identification, Polychlorinated biphenyls, Tetrachlorodibenzo-p-dioxin, *Michigan.

Four to 695 ppt of 2,3,7,8-tetrachlorodibenzo-p-dioxin were found in the edible flesh of fresh water fish taken from several bodies of water in Michigan (Tittabawassee, Grand, and Saginaw Rivers, Lake Michigan, and Saginaw Bay). Twenty-six of 36 samples contained detectable quantities of this compound. Ten of the 36 samples contained levels higher than 40 ppt. Bottom feeders (catfish and carp) had higher concentrations than bass, perch, and suckers. Analysis was done by high resolution gas chromatography-high resolution mass spectrometry. Other compounds qualitatively identified in fish tissue were: chlorinated diphenyl ethers, trichlorohydroxybenzylphenyl ether, tetrachlorodibenzofurans, trichloroterphenyl, polychlorinated biphenyls, and tri- and penta-chlorodibenzo-p-dioxins. The source of this contamination was not known. (Cassar-FRC)

DETERMINATION OF SULFATE IN RIVER WATER BY FLOW INJECTION ANALYSIS,
Okayama Univ. (Japan). Dept. of Chemistry.
O. Kondo, H. Miyata, and K. Toei.
Analytica Chimica Acta, Vol 134, p 353-358, 1982. 3 Fig, 2 Tab, 11 Ref.

Descriptors: *Sulfates, *Water analysis, Chemical analysis, Measuring instruments, *Pollutant identification, Rivers, Water quality, Monitoring.

The determination of sulfate ion by flow injection analysis (f.i.a.) using the barium chelate of sulfonazo-III or dimethylsulfonazo-III is reported. The method can be used for 1-30 ppm sulfate ion in river water, which range covers almost all river waters in Japan. Thirty samples can be determined per hour within 1% relative error. The flow rates of the reagent solution and barium sulfate solutions are optimally 2 ml/minute each. Sample solutions are filtered through a Millipore filter and passed through an Amberlite IR120-B column before being injected. From the sample loop, 80 microliters of treated sample solution is injected into the carrier stream. Peak heights are measured at 645 nm for the sulfonazo-III method and at 662 nm for the DMSA-III method. The concentration of sulfate ion is measured from a calibration graph prepared with potassium sulfate standards. The absorption spectra of sulfonzao-III and its barium chelate show maxima at 575 nm and 643 nm, respectively. Absorbance is measured at 645 nm for greatest sensitivity. The effects of co-existing ions were investigated. Calcium ions in ordinary river water interfere with the determination. To prevent this, samples are first passed through a column of cation-exchange resin. The procedure was applied to the determination of sulfate in waters from the Asahi, the Yoshii and the Takahashi Rivers in Okayama Prefecture. Recovery tests indicate that the method was not affected by the various matters dissolved in these river waters. (Baker-FRC)

COMPARISON OF ATOMIC ABSORPTION SPECTROMETRIC, SPECTROPHOTOMETRIC, AND FLUORIMETRIC METHODS FOR DETERMINATION OF ALUMINUM IN WATER,
McMaster Univ., Hamilton (Ontario). Dept. of Geology.
R. Playle, J. Gleed, R. Jonasson, and J. R. Kramer.
Analytica Chimica Acta, Vol 134, p 369-373, 1982. 20 Ref.

Descriptors: *Aluminum, *Pollutant identification, Water quality, Water pollution control, Atomic absorption spectrometry, Spectrophotometry, Measuring instruments, Water analysis, Trace metals, *Comparison studies.

The ferron colorimetric method, the lumogallion fluorimetric method, and the electrothermal atomic absorption spectrometry (a.a.s.) method are compared for determining the aluminum content in water. Interferences for each method are described. It was found that in the three methods, standard additions generally gave more reliable results than calibrations against a standard curve. The ferron method gave unreliable results below about 50 micrograms/liter, while the lumogallion and a.a.s. methods yield similar results. When a large difference between these latter two methods occurred, it may have been due to the fact that a.a.s. measures total aluminum, while the lumogallion method does not measure unreactive aluminum. Natural kaolinite was selected as a representative refractory material to test the assumption that electrothermal a.a.s. quantified total aluminum in an aqueous sample. The electrothermal a.a.s. method is assumed free of interferences and has an applicable range of 10 to above 1000 micrograms aluminum/liter. The colorimetric ferron method has multiple interferences and is useful in the 50-1500 microgram aluminum/liter range. The fluorimetric method has few important interferences and is useful to below 1 microgram aluminum/liter. (Baker-FRC)

DETERMINATION OF TRACE METALS IN ESTUARINE SEDIMENTS BY GRAPHITE-FURNACE ATOMIC ABSORPTION SPECTROMETRY,
National Research Council of Canada, Ottawa (Ontario). Div of Chemistry.
R. E. Sturgeon, J. A. H. Desauliniers, S. S. Berman, and D. S. Russell.
Analytica Chemica Acta, Vol, 134, p 283-291, 1982. 7 Tab, 24 Ref.

Descriptors: *Sediments, *Trace metals, Estuarine environments, *Estuaries, Sedimentation, Atomic absorption spectrometry, *Pollutant identification, Copper, Cobalt, Chromium, Lead, Nickel, Berryllium.

LIBRARY U. Of I., URBANA-CHAMPAIGN

This report details a description of procedures which permitted the accurate determination of cadium, lead, cobalt, copper, chromium nickel and beryllium in estuarine sediments by graphite furnace atomic absorption spectrometry in combination with the L'vov Platform. The technique is interference free and permits calibration with simple aqueous solutions of metal standards. Results for lead and copper appear to be biased on the low side of acceptability. Quantitative dissolution and recovery of chromium in both sediment samples examined was evident, indicating that complete dissolution of chromium-bearing minerals was achieved and that no significant loss of volatile CrOC12 species occurred. THE USE OF XAD-RESINS FOR THE DETECTION OF MUTAGENIC ACTIVITY IN WATER. II. STUDIES WITH DRINKING WATER,
Rijksinstituut voor Drinkwatervoorziening, Leidschendam (Netherlands). Chemical Biological Div.
H. J. Kool, C. F. van Kreijl, and H. J. van Kranen.
Chemosphere, Vol 10, No 1, p 99-108, January, 1981. 4 Fig, 3 Tab, 17 Ref.

Descriptors: *Ion exchange, *Mutagens, *Water analysis, Pollutant identification, Drinking water, Organic matter, *Netherlands, *Water supply, Rhine River, Meuse River.

The ion exhange method for concentrating mutagens in water, described in Part 1 of the work, was successfully applid to the anlaysis of drinking water from 6 Netherlands cities which derive their water from the Rhine and Meuse Rivers. Water from 4 of the cities showed dose-related responses. The type of mutagen mutations induced (TA98 or TA100) was different among the different cities. Water from 2 cities did not produce any mutagenic activity in the test. It is likely that the treatment processes used in these cities effectively remove organic mutagens present in the raw water supply. (Cassar-FRC)

USE OF XAD-RESINS FOR THE DETECTION OF MUTAGENIC ACTIVITY IN WATER. I. STUDIES WITH SURFACE WATER,
Rijksinstituut voor Drinkwatervoorziening, Leidschendam (Netherlands). Chemical Biological Div.
H. J. Kool, C. F. van Kreijl, H. J. van Kranen, and E. de Greef.
Chemosphere, Vol 10, No 1, p 85-98, January, 1981. 6 Fig, 2 Tab, 25 Ref.

Descriptors: *Ion exchange, *Mutagens, *Water analysis, Rivers, Organic matter, *Pollutant identification, Surface water, *Netherlands.

An equal mixture of XAD-4 and -8 resins and dimethyl sulfoxide as an elutant were most suitable for concentration of mutagens in surface waters. Optimal flow rates were 2-4 bed volumes per minute. Most mutagenic substances were adsorbed at a neutral pH, except for a minor fraction which was adsorbed at pH 3. The mutagenic activity of the concentrate produced by XAD resin adsorption and of a concentrate prepared by freeze drying were similar. The method was tested on water from several rivers (Rhine, Meuse, and Biesbosch), wastewater plant effluent, and seawater from nearshore North Sea. (Cassar-FRC)

ANALYSIS OF PCBS IN SEDIMENT BY GLASS CAPILLARY GAS CHROMATOGRAPHY,
Rijksinstituut voor Visserijonderzoek,Ijmuiden (Netherlands).
M. A. T. Kerkhoff, A. de Vries, R. C. C. Wegman, and A. W. M. Hofstee.
Chemosphere, Vol 11, No 2, p 165-174, 1982. 2 Fig, 4 Tab, 14 Ref.

Descriptors: *Polychlorinated biphenyls, Sediments, *Gas chromatography, *Pollutant identification, Chlorinated hydrocarbons, Rivers, *Rhine River, Aroclors, Organic compounds, Aromatic compounds.

Sediment samples from the Rhine River and its tributaries were analyzed for polychlorinated biphenyls (PCB) by glass capillary gas chromatography. Sediment samples from 6 rivers contained from 1.0 to 3.9 mg per kg total PCB as determined by the capillary method. The perchlorination method, which converts all PCB's to the decachlorobiphenyl, produced results 1.1 to 3.7 times higher than those obtained by the capillary gas chromatograph. Mean recovery of 13 individual components of Aroclor 1242 was over 85% in spiked samples. Seventeen individual components were identified. The glass capillary gas chromatographic method, which provides information on individual PCB components, may be useful in identifying sources of contamination. (Cassar-FRC)

COPROSTANOL AND BACTERIAL INDICATORS OF FAECAL POLLUTION IN THE SCHELDT ESTUARY,
Institut d'Hygiene et d'Epidemiologie, Brussels (Belgium).
M. Yde, E. De Wulf, S. De Maeyer-Cleempoel, and D. Quaghebeur.
Bulletin of Environmental Contamination and Toxicology, Vol 28, No 2, p 129-134, February, 1982. 1 Fig, 2 Tab, 11 Ref.

Descriptors: *Coprostanol, *Indicators, *Bacteria, Pollutant identification, Bioindicators, *Coliforms, *Scheldt Estuary, Streptococcus, Clostridium, Sewage bacteria, Feces, Netherlands, Belgium.

Coprostanol (5-beta-cholestan-3-beta-ol), a steroid present in animal and human feces, was tested as an indicator of fecal pollution in waters of the Scheldt estuary (The Netherlands-Belgium). Analysis was performed by conversion to the trimethylsilyl derivative, followed by gas chromatography using a flame ionization detector and glass capillary column. For comparison, total coliforms, fecal coliforms, fecal streptococci, and sulfite-reducing clostridia were determined. Coprostanol levels were not as reliable as the bacterial indicators in determining fecal pollution. In some samples bacteria were detected but coprostanol was below the detection limit. However, coprostanol analysis may be useful in determining fecal pollution in waters where bacteria have been destroyed by thermal pollution or toxic substances, by low temperatures, or by a delay between sampling and analysis. (Cassar-FRC)

AUTOMATED TURBIDIMETRIC DETERMINATION OF SULPHATE IN SURFACE, GROUND AND DOMESTIC WATER BY FLOW-INJECTION ANALYSIS,
Pretoria Univ., (South Africa). Dept. of Chemistry.
J. F. Van Staden.
Fresenius Zeitschrift fur Analytische Chemie, Vol 310, No 3/4, p 239-242, 1982. 2 Fig, 2 Tab, 8 Ref.

Descriptors: *Water analysis, *Sulfates, Chemical analyis, *Pollutant identification, Flow injection analysis, *Turbidity, Surface waters, Groundwater, Drinking water.

A flow-injection procedure is reported in which one sampling loop of a two-position sampling valve is used to sample an alkaline buffer-EDTA solution alternating with water samples picked up on the other loop, obviating acidification of water samples and reducing baseline drift. The procedure as described is suitable for carrying out sulfate analysis at a rate of about 60 water samples per hour. The alkaline buffer-EDTA solution dissolves any residual precipitate coating the walls of the flow cell and keeps the system clean. The coefficient of variation is better than 0.95%. The reproducibility of the method was tested on standard sulfate solutions and water samples. (Baker-FRC)

DATA ACQUISITION AND EVALUATION IN BIOLOGICAL MONITORING SYSTEMS,
Virginia Polytechnic Inst. and State Univ., Blacksburg. Center for Environmental Studies.
D. Gruber, and J. Cairns.
Hydrobiologia, Vol 83, No 3, p 387-393, 1981. 2 Fig, 25 Ref.

Descriptors: *Water quality, *Monitoring, *Bioindicators, Pollutant identification, Indicators, Behavior, Respiration, Water pollution control, Wastewater, Computers, Automation, *Fish, Data acquisition, Data interpretation.

The ventilatory rates of fish may be used in biological monitoring for continuous and automated pollutant detection. Over the past 15 years many studies have used the ventilatory behavior of fish to assess wastewater quality. A variety of ventilatory parameters have been measured, including ventilatory frequency, ventilatory amplitude, and gill purges or coughs. Methods developed for receiving the ventilatory signals have incorporated manometric techniques, attached electrodes, unattached electrodes, and visual observation. The most suitable method for industrial use incorporated noncontact submerged electrodes. Strip chart recorders have typically been utilized for fish ventilatory signal acquisition, as they are relatively inexpensive, are easily interfaced to electrodes, and provide a hard copy of the data. Some systems allow the ventilatory rates of 12 fish to be accumulated continuously with the aid of an online minicomputer. It is important that differences among fish be considered when analyzing ventilatory behavior. The static baseline approach to data handling is discussed, along with a time series approximation. Widespread application of on-line biomonitoring systems will almost certainly require computer technology. The incorporation of computer based biomonitoring apparatus facilitates collections of data from many fish almost continuously. The computer can be programmed to trigger a water sampler whenever the fish are behaving abnormally. (Baker-FRC)

THE USE OF THE THREE-RIDGE CLAM (AMBLEMA PERPLICATA) TO MONITOR TRACE METAL CONTAMINATION,
Purdue Univ., Lafayette, IN. School of Pharmacy and Pharmacal Sciences.
T. G. Adams, G. J. Atchison, and R. J. Vetter.
Hydrobiologia, Vol 83, No 1, p 67-72, 1981. 5 Fig, 1 Tab, 20 Ref.

Descriptors: *Bioindicators, *Rivers, Industrial wastes, Indicators, Pollutant identification, Clams, Water pollution, *Zinc, *Cadmium, *Electroplating, *India.

The use of the three-ridge clam as a monitor of zinc and cadmium contamination in two freshwater streams was evaluated. The streams, Williamson Ditch and Trimble Creek, are located in northcentral India. An electroplating plant discharges wastes that contain zinc and cadmium into Williamson Ditch about 3 km from Palestine Lake. Clams were collected from a relatively uncontaminated area in one river and transported to four study sites in the two contaminated streams. The clams were placed into polyethylene cages and left in these streams for one week. Control clams were treated in a similar manner and left in the uncontaminated river. The highest mean concentration of zinc was 956 micrograms/gram dry weight and was found in the gill tissue of clams from the most contaminated site. The highest mean cadmium concentration, 18.6 micrograms/gram dry weight, was found in the digestive glands, also from the most contaminated site. Mean concentrations at contaminated sites were signigicantly higher than background and control levels. These findings suggest that these particular organs of clams may be useful in monitoring levels of zinc and cadmium in other freshwater systems. (Baker-FRC)

THE EFFECTS OF DISSOLVED HEAVY METALS ON ATTACHED DIATOMS IN THE UINTAH BASIN OF UTAH, U.S.A.,
Brigham Young Univ., Provo, UT. Dept. of Botany and Range Science.
S. R. Rushforth, J. D. Brotherson, N. Fungladda, and W. E. Evenson.
Hydrobiologia, Vol 83, No 2 p 313-323, 1981. 2 Fig, 4 Tab, 36 Ref.

Descriptors: *Heavy metals, *Diatoms, Basins, *Utah, Streams, River basins, Chemical properties, Water analysis, Bioindicators, *Ecological effects.

A study was performed to examine how diatoms differ in their response to heavy metal concentrations in natural systems. Initial data was also collected on the response to heavy metals of important diatom species in order to suggest further autecological studies. Samples of diatom populations were collected from 22 sites along selected streams in the Uintah Basin of Utah during 1977-1978. Seasonal changes in the concentrations of heavy metals were noted. The trends noted were largely due to runoff patterns and characteristics of the river drainage basins. The study demonstrated that under field conditions several diatom species showed different patterns of abundance with varying concentrations of heavy metals. Such responses were shown to be probably related to seasonal differences. This is due to the fact that environmental factors do not operate separately from one another, but rather in some sort of interaction, be it complememtary or antagonistic. Thus the effects of heavy metals on diatom species would be expected to be mitigated by other environmental parameters, such as day length, temperature, nutrients of water hardness. Achnanthes minutissima, Cylotella meneghiniana, Cymbella minuta, Gomphonema parvulum, Navicula secreta var. apiculata, Nitzschia frustulum, Nitzschia frustulum var. perminuta, Nitzschia pale, and Synedra ulna appear to be indicator species of high or low heavy metal concentrations. Other species also demonstrated meaningful relationships to high or low heavy metal concentrations. (Baker-FRC)

INFLUENCE OF CHLORINATION AND THE DISTRIBUTION SYSTEM ON MUTAGENS IN A POTABLE WATER SUPPLY,
Illinois Univ. at Urbana-Champaign. Dept. of Civil Engineering.
J. B. Johnston, and R. R. Clark.
Available from the National Technical Information Service, Springfield, VA 22161 as PB82-220674, Price codes: A07 in paper copy, A01 in microfiche. Research Report No 168, March 1982, 137 p, 33 Tab, 26 Fig, 53 Ref, 2 Append. OWRT B-125-ILL(1). USDI 14-01-0001-9148.

Descriptors: Ames assay, *Chlorination, Distribution system, *Mutagens, Polynuclear aromatic hydrocarbons, *Potable water, *Water supply systems.

A growing number of studies have detected mutagens in public water supplies. This study examined a central Illinois public water supply and found the presence of mutagens dependent on mammalian metabolism (promutagens) in addition to chlorination-related, direct-acting mutagens. Both kinds of mutagens were recovered by adsorption on polyurethane foam and quantitated by the Ames Salmonella/microsome reversion assay. It was found that the pro-mutagens first appeared in the distribution system (following treatment) and that the direct-acting activity increased somewhat within the system. It was found that chloramine disinfection produced water with more protomutagenic activity than direct-acting mutagenicity and that chlorination beyond break-point reversed this order. Detailed study of the time of appearance of mutagens and chlorine residuals showed patterns consistent with the formation of direct-acting mutagens by reaction of the free chlorine residual with substances in the water - possibly materials contributed by the distribution system. Particulate matter collected from hydrant flush water at dead ends in the distribution system were found to harbor high amounts of two known carcinogens and other unidentified mutagenic substances. These high levels of mutagens were not found in tap water, nor could the carcinogens be identified in the tap water.

QUANTIFICATION OF OCTACHLOROSTYRENE AND RELATED COMPOUNDS IN GREAT LAKES FISH BY GAS CHROMATOGRAPHY-MASS SPECTROMETRY,
Environmental Research Lab.-Duluth, MN.
D. W. Kuehl, K. L. Johnson, B. C. Butterworth, E. N. Leonard, and G. D. Veith.
Journal of Great Lakes Research, Vol 7, No 3, p 330-335, 1981. 1 Fig, 2 Tab, 14 Ref.

Descriptors: *Fish, *Chemical analysis, *Chlorinated compounds, *Great Lakes, Gas chromatography, Mass spectrometry, Octachlorostyrene, *Pollutant identification.

Studies have been underway since 1974 on gas chromatographic-mass spectrometric (GC-MS) exploration of organic chemical residues in composite samples of fishes from major watersheds in the United States. A large bank of fish tissue samples was established. These samples were utilized to estimate the levels of octachlorostyrene and related polychlorinated hydrocarbons in Great Lakes fish. Whole fish were composited, ground, dried with anhydrous sodium sulfate, and extracted with hexane. The extract was concentrated, cleaned up on a Florisil column, and analyzed by multiple ion detection of two ions for each compound on a computerized system with peak-finding and quantification software. The results indicate that octachlorostyrene residues in fish from the two uppoer lakes, Superior and Michigan, were below the detection limit of 5 ng/g (wet weight), while residues in fish from Lakes Huron, Ontario and Erie reached as high as 400 ng/g. Fish from the Ashtabula River/Field Brook area contained extremely large quantities of octachlorostyrene and other chlorinated compounds, suggesting specific industries as the source of these pollutants. ON THE USE OF FILTERS FOR DISTINGUISHING BETWEEN DISSOLVED AND PARTICULATE FRACTIONS IN NATURAL WATERS,
Chalmers Univ. of Technology, Goeteborg (Sweden). Dept. of Analytical and Marine Chemistry.
L. G. Danielsson.
Water Research, Vol 16, No 2, p 179-182, February, 1982. 2 Fig, 16 Ref.

Descriptors: *Filtration, *Natural waters, Water, Colloids, Water quality, Iron, Heavy metals, Pore size, Particulate matter, Lakes, Bogs, Estuaries, Marshes, Swamps, *Lake Alenashalan, Sweden.

The effects of filtration on colloidal matter present in natural waters were investigated. Samples were taken from Lake Alenashalan in southwestern Sweden. The lake is surrounded by peat bogs and is high in concentration of iron and humic substances. Even though these substances are present in high concentrations here, the compounds responsible for them are present in most natural waters. The nature of these compounds is probably a co-colloid of iron hydroxide and organic compounds. The two types of membrane filters used in the study have widely different construction. Millipore filters are made of a copolymer of cellulose nitrate and cellulose acetate, forming a three dimensional net. The specified pore size is actually a mean value. Nucleopore filters have a somewhat better defined pore size, as these filters are made by perforating a sheet of polycarbonate in a well defined way. The filtration characteristics are, however, rather similar for the two filters. The use of filters of normal pore sized (0.4 to 0.7 micrometers) is inadequate for the separation of particulate and truly dissolved fractions of metals in natural waters, especially for colloid-laden samples such as bog waters, woodland streams and lakes, and estuarine waters. Use of membrane filters for the removal of large particles from a water sample can introduce large errors due to the changing effective pore size caused by clogging. For large volume filtrations, frequent filter change and/or large area filters should be used. Filter holders supplied with stirrers like those used for ultrafiltration might also be beneficial in helping to avoid clogging. (Baker-FRC)

BIOLOGICAL MONITORING, PART IIA - RECEIVING SYSTEM FUNCTIONAL METHODS, RELATIONSHIPS AND INDICES,
Virginia Polytechnic Inst. and State Univ., Blacksburg. Dept. of Biology.
R. A. Matthews, A. L. Buikema, Jr., J. Cairns,Jr., and J. H. Rodgers, Jr.
Water Research, Vol 16, No 2, p 129-139, February, 1982. 1 Tab, 113 Ref.

Descriptors: *Monitoring, *Reviews, Ecosystems, Stres, Water quality, Water resources development, Stress analysis, *Biological properties, *Environmental effects.

Biological monitoring is defined as the systematic use of biological responses to evaluate changes in the environment with the intent to use this information in a quality control program. Biological monitoring is reviewed primarily from the functional aspect, integrating structure and function into a more complete picture of exosystem response to stress. Ecosystem structure considers the composition of the biological community, including species, numbers, biomass, life history and spatial distribution of populations, the quantity and distribution of the abiotic materials, and the range or conditions of existence. Function is concerned with the rate of biological energy flow through the ecosystem, the rate of material or nutrient cycling, biological or ecological regulation, and regulation of the environment by the organisms. Functional responses to stress in aquatic systems can be studied by photosynthesis and respiration measurements taken at the population level or higher. Physicochemical measurements, behavioral changes, and changes in physiological functions such as nitrogen fixation and electron transport can also be used as measurements. Effective biomonitoring should emphasize a combined structure/function testing strategy. A holistic evaluation should include the measurements of both biotic and abiotic structural and functional parameters, should include community and higher level biomonitoring tests in testing strategies, and should include comparison studies between microcosms and field systems. A high correlation between microcosm and field responses would allow effluent hazard evaluations to be made with the least amount of risk. (Baker-FRC)

VIRAL POLLUTION DETERMINATION OF SUPERFICIAL WATERS (RIVER WATER AND SEA-WATER) FROM THE URBAN AREA OF BARCELONA (SPAIN),
Barcelona Univ. (Spain). Dept. de Microbiologia.
F. Lucena, C. Finance, J. Jofre, J. Sancho, and L. Schwartzbrod.
Water Research, Vol 16, No 2, p 173-177, February, 1982. 3 Tab, 21 Ref.

Descriptors: *Water quality, *Measuring instruments, Rivers, Marine environment, Bacteria, *Viruses, Public health, Human diseases, *Spain, Municipal wastes, *Surface water.

A survey of virus occurrence was performed using the method of adsorption onto glass powder for concentrating the virus in a variety of aquatic systems located in the metropolitan area of Barcelona, Spain, including two rivers and three beaches. Samples were always collected from a depth of 30 cm. Viruses were recovered from all samples. Values were high and ranged from 18.4 to 55 most probable number of cytopathogenic units (MPNCU)/liter in the samples corresponding to the Besos River and from 0.44 to 44 MPNCU/liter from the Llobregat River. Levels of viruses in the Besos were about 10 times higher than the values from the Llobregat River. corresponding to other parameters of pollution. Viruses were also recovered in all samples from the three marine locations

LIBRARY U. OF I., URBANA-CHAMPAIGN

near the beaches. The viruses spread far from the shore, since the number of viruses recovered from samples taken 2, 5, 20, and 1,000 meters from the outfall did not differ significantly. The percentage of positive assays decreased in June. These findings confirm that current methods for determining the microbial quality of coastal sea-waters used for recreational purposes such as bathing and sailing are inapplicable to viruses. The findings also indicate that the survival time of viruses in sea water is longer than the survival time of bacteria. (Baker-FRC)

GC/MS ANALYSIS OF XAD-2 EXTRACTS OF SUPERCHLORINATED SEPTAGE,
North Texas State Univ., Denton. Dept. of Chemistry.
J. E. Henderson, and W. H. Glaze.
Water Research, Vol 16, No 2, p 211-218, February, 1982. 7 Fig, 2 Tab, 21 Ref.

Descriptors: *Chlorination,*Wastewater treatment, Municipal wastewater, Public health, Chlorinated hydrocarbons, *Organic compounds, *Mass spectrometry.

A new mass spectral search system is presented for the detection of chlorinated and brominated organic compounds formed by the superchlorination of a septage. Samples of raw and superchlorinated septage were used. Many of the halocarbons found in this study are structurally similar and in may cases identical to compounds formed from the chlorination of humic material and surface water organics. Compounds detected through a purge and trap analysis included methylene chloride, acetone, diethylether, acetic acid, 1,1-dichloroethane, chloroform, 1,1,1-trichloroethane, alpha,alpha,beta-trichloropropionitrile, toluene, chlorobenzene, chlorotoluene, and dichlorobenzene. Compounds determined through microcoulometric analysis of XAD-resin/ether extracts included chloroform, dichlorobenzene, tetrachloroacetone, dichlorobenzene, chlorobutendione-3, dichlorotoluene, and trichlorotoluene. It is suggested that neutral chloro-aromatics result from the decarboxylation of the corresponding aromatic acids that are formed during oxidative cleavage of the humic polymer. Whether chlorination occurs before or after oxidative cleavage of the polymer or both is not clear. Nor is it clear that a radical chlorine intermediate is responsible for the decarboxylation process. It is concluded that the major chlorinated compounds from the chlorination of municipal wastewaters appear to result from chlorination and degradation of humic substances present in the water and bear striking resemblance to products obtained from natural humics and model compounds thought to be constituents of humic and fulvic acid. MEASUREMENT OF EFFECTS OF CARBARYL IN SURFACE WATER ON FECAL POLLUTION INDICATOR BACTERIA BY USE OF PLATE COUNTS AND RESPIROMETRY,
Texas Univ., Houston. School of Public Health.
U. A. Anugwelem, and R. K. Guthrie.
Water Research, Vol 16, No 2, p 219-221, February, 1982, 2 Fig, 16 Ref.

Descriptors: *Water quality, *Monitoring, Public health, *Carbaryl, Pesticides, Insecticides, Bioindicators, Indicators, *Escherichia coli, Streptococcus faecalis, *Bacteria.

The objectives of the present study were to determine the responses of Escherichia coli and Streptococcus faecalis to the presence of low concentrations of carbaryl, as measured by plate counts; to assess changes in numbers of viable organisms; and by Warburg respirometry, to assess changes in metabolic rates. The results of the study indicate that the presence of carbaryl in surface water would cause a more rapid die-off of these indicator organisms, with S. faecalis dying off more rapidly than E. coli. If this occurred in a polluted water source it could result in false or misleading conclusions, as Geldreich has suggested that the presence of certain fecal streptococci indicates recent fecal pollution of water and other investigators have reported that these organisms survive longer in water than do coliforms. To provide a different measure of the effects of carbaryl on these fecal pollution indicators, oxygen uptake as measured by Warburg respirometry was determined. Oxygen uptake by pure cultures of E. coli in the presence of 1 mg/liter carbaryl was significantly increased as compared to uptake by E. coli controls. Oxygen consumption by pure cultures of S. faecalis was decreased significantly in the presence of both 1 and 5 mg/liter carbaryl. The data indicate the desirability of using more than one method when seeking to determine the effect of chemicals on microorganisms, as the fecal results obtained by the two methods here appeared to be contradictory until the early data from plate counts were considered and the different results in early and late time frames were noted. A SIMPLE AND RAPID METHOD FOR THE DETERMINATION OF LEAD AND CADMIUM IN SEDIMENT BY GRAPHITE FURNACE ATOMIC ABSORPTION SPECTROMETRY,
Central Research Inst. of Electric Power Industry, Tokyo (Japan).
M. Sakata, and O. Shimoda.
Water Research, Vol 16, No 2, p 231-235, February, 1982. 1 Fig, 6 Tab, 10 Ref.

Descriptors: *Sediments, *Pollutant identification, *Cadmium, *Lead, Spectroscopy, *Atomic absorption spectroscopy, Chemical analysis, Sedimentation.

A simple and rapid method is presented for the routine determination of lead and cadmium in sediment using graphite furnace atomic absorption spectrometry. Sample solutions are injected into the graphite furnace by means of an automatic sampling device for the rapid and simple analyses. The automated analysis procedure has better precision than the manually per formed method. Dry sediment is digested for 1 hr at 140 C with a mixture of hydrogen fluoride, nitric acid, and hydrochloric acid in the Teflon-lined bomb. Severe interference was offered by several major elements, including sodium and potassium. However, such disturbances can be overcome by adding to the sample a 1% solution of ammonium phosphate in the same volume as the sample solution for lead and 1% ammonium sulfate for cadmium as matrix modifiers. In thirty-six sediments taken from 13 reservoirs in remoter areas of Japan, the average contents of lead and cadmium were 35 and 0.40 ppm for cadmium on the basis of dry sediment. The proposed method is applicable to the routine determination of a large number of sediments with minimal effort. (Baker-FRC)

BIOLOGICAL MONITORING, PART III.- RECEIVING SYSTEM METHODOLOGY BASED ON COMMUNITY STRUCTURE,
Illinois Univ. at Urbana-Champaign. Dept. of Civil Engineering.
E. E. Herricks, and J. Cairns, Jr.
Water Research, Vol 16, No 2, p 141-153, 1982. 2 Fig, 1 Tab, 104 Ref.

Descriptors: *Monitoring, *Reviews, Water quality, *Ecosystems, Aquatic life, Aquatic habitats, Data collections, Data acquisition, Aquatic life, Biological samples, *Pollutant identification.

The use and limitations of data that describe the structure of aquatic communities are discussed, first in terms of data resources and the range of analysis techniques available, then in terms of interpretative methodologies for input to management and protection decisions, including limits that should be placed on data. The analysis of aquatic ecosystem structure requires identification and enumeration of community elements. Procedures which facilitate extraction off information follow classical investigative approaches that require formulation of a hypothesis followed by data collection and analysis to support or nullify the hypothesis. The procedures that employ structural analysis methodologies are based on the theory of species abundance relationships as well as community identification based on indicator, target, or keystone species. Monitoring programs can be categorized as descriptive or analytical. Descriptive approaches include biomonitoring designs which establish baselines, identify trends, and only allow inference of cause-effect relationships. Both descriptive and analytical biomonitoring are dependent on data analysis procedures. Specific sample analysis procedures are dependent on the quality and thoroughness of both the collection procedures and processing and identification of samples . Multiply sample analysis allows comparisons to be made between samples. The capacity to discriminate between samples and the importance of identifying why sample differences occur is the goal of aquatic community biomonitoring. The goal of biomonitoring efforts should be the development of information resources that will allow decision making based on certainty of cause-effect relationships. This can be achieved through a conjunction of descriptive and analytical approaches to community structure biomonitoring. (Baker-FRC)

DETERMINATION OF CADMIUM IN LAKE MICHIGAN BY MASS SPECTROMETRIC ISOTOPE DILUTION ANALYSIS OR ATOMIC ABSORPTION SPECTROMETRY FOLLOWING ELECTRODEPOSITION,
Argonne National Lab., IL.
J. Muhlbaler, C. Stevens, D. Graczyk, and T. Tisue.
Analytical Chemistry, Vol 54, No 3, p 496-499, March, 1982. 2 Fig, 3 Tab, 17 Ref.

Descriptors: *Cadmium, *Water analysis, Lakes, *Lake Michigan, Chemical analysis, *Mass spectrometry, Atomic absorption spectrometry, Electrodeposition, Mass spectrometric isotope dilution.

Mass spectrometric isotope dilution analysis was used to assess the efficiency of the electrodeposition and stripping procedure described and to study control of contamination in sampling and handling operations in attempts to determine cadmium concentration levels in Lake Michigan. One of the goals of the study was therefore to evaluate the suitability of electrodeposition for routine use as a means of preconcentrating cadmium prior to atomic absorption analysis. When specific precautions were taken, the electrodeposition-MSID combination proved suitable, yielding a concentrate that is free of significant interferences and giving steady ion currents from samples and blanks containing 25-100 ng total cadmium. In practice, the lower working limit was determined by the blank value rather than by the inherent sensitivity. It is the variability introduced by contamination that appears to control the overall precision. The most persistent and troublesome source of this contamination was cadmium-laden particulate matter in the laboratory and shipboard atmospheres. Use of closed containers and clean air work stations was effective in dealing with these problems. When using MSID, the calculated instrumental limit of detection was less than 0.1 ng, well below the limits imposed by the observed precision and blank values. The overall procedure had a precision of 14% relative standard deviation. Electrothermal atomic absorption spectrometric detection gave a relative precision of 19%. The main cadmium concentration in Lake Michigan water samples collected in 1978 ranged from 31 to 41 ng/liter. (Baker-FRC)
